SECURITY RELEASE OF LECTURE ON C. I.

Mr. Friedman

ATSA-OOA

MATE 30 Jan. 1951

COMMENT NO. 1

ESL Goodwin/meb/335

The draft of the lecture on Communications Intelligence given by you before the faculty and students of Class 50-B, Air Communication and Electronic Staff Officers' Course, on 29 September 1950 is approved for delivery, under the classification of SECRET, at the Air Command and Staff School, Maxwell AFB, on 2 February 1951.

S. P. COLLINS Colonel, Signal Corps Deputy Director, AFSA

CONFIDENTIAL

# REF ID:A66402

#### COMMUNICATIONS INTELLIGENCE

A presentation by Mr. William F. Friedman to the Faculty and Students of Class 50-B, Air Communication & Electronic Staff Officers' Course, on 29 September 1950

Carlo Jan Mil

Colonel Sheets, Gentlemen: First I want to assure you of my approciation of the opportunity to come here to talk to you on my subject. In inviting me to speak on the subject of Communications Intelligence, it was indicated that "the objective of the presentation is to create an awareness of the background, development, and manner of employment of this vital military weapon." Communications Intelligence was not always regarded as vital. I am reminded here of a story that I read some years ago in an old book, and the story may be apogryphal, but I give it for what it is worth. It seems that about two thousand years ago there was a Persian queen whose name was Semiramis and who took an interest in cryptography. Whether it was because of that interest or other unnatural. circumstances, the record doesn't say, but anyhow she met an untimely death. Pregunably she went to Heaven, or perhaps to the other place, but having left instructions as to the disposition of her remains, they built for her an imposing mausoleum in which her sarconhagus rested. On the outside of the mausoleum there was carved a message, which said, "Stay, weary traveler! If thou art footsore, hungry, or in need of money, unlock the riddle of the eigher graven below, and you will be lead to riches beyond all dreams of avarice." Then underneath it there was a oryptogram. For several hundred years the possibility of sudden wealth served as a lure to all the experts who tried their hands at deciphering the message, but they were without success, until one day, presumably,

along came a long-whiskered, bespectacled individual who, after working at it for a considerable length of time, solved the message. It gave him detailed instructions for making a secret entry into the tomb.

When he got inside he found an instruction to open the sarcophagus, but he had to solve another message in order to do so. Possibly it involved finding the correct combination to a 5-tumbler look! Well, he solved that one too, after a lot of work, and opened the sarcophagus and found a box. In the box was a message in plain language, and this is what it said: "Ch, thou wile and insatiable monster, to disturb these poor bones! If thou hadst learned something more useful than the art of deciphering, thou wouldst not be footsore, hungry, or in need of money!" Heavy times in the course of the past thirty years I have had occasion to wish that I know the old gal's address so that I could put as a first indorsement to the basic communication the single word "Concur." Well, anyhow, it's been an interesting life, if not financially lucrative.

Now I am going to read you a short paragraph from <u>Time Magazine</u> of December 17, 1965. "Magic is the Word for It"

most potent secret weapon of World War II was not radar, not the VT fuse, not the atom bomb, but a harmless little machine which cryptographers painstakingly constructed in a hidden room in Washington. With this machine, failt after years of trial and error, of inference and deduction, cryptographers have duplicated the decoding devices used in Tokyo. Testimony before the Pearl Harbor Committee had already shown that the machine known as 'Magic' was in use long before December 7, 1941,

#### REF ID: A66402

had given ample warning of the Japs' sneak attack if only U.S. brass hats had been smart enough to realize it. General Marshall now continued the story of 'Magic's' magic."

and then it goes on to say what that story was. I hope I'll have time to return to it a little bit later on.

I hardly need to stress the necessity for secrecy in this business. Hope for future success depends to a very great degree on maintaining secrecy with respect to past achievements. Changes as a result of suspected compromise of cryptographic systems are easy to make and very hard to follow. The effects of leakage or compromise are not local - they are widespread, because of the widespread use and distribution of particular cryptographic systems. During World War II, I might say, the continuance of our success hung by a very elender thread. I am respinded at this point of an instance of this sort which happened just a short time before 1941, and to avoid maming names I will simply say that there was a chap in a certain capitol of the world who sent a message to his home government in which he said that he was getting a bit worried about their communications. In substance, his said: "You know, these many telegraphic exchanges that we are having, dealing with this matter in hand, have put a great strain on our cipher system because they have made it necessary to be very voluminous in our correspondence, so that I am afraid that perhaps some third party might be reading our communications. I think we ought to do semething about this right away." Well, we read that, and we were very such upset for fear that they would take the hint and that something would happen. So we were on tenterhooks and pins and needles for two or three days until we got the reply from headquarters. You can imagine how agog with expitement we were

REF ID:A66402

until the mossage was processed to the point of intelligibility. To paraphrase the reply, it said, "Well, you southern extremity of a horse's anatomy, don't you realize that what you are saying is way out of line? Don't you know that our system and the machine has so many permutations and combinations it's inconceivable that anybody should be able to read these communications without having the machine and the key? Now, don't you worry any more about it. You 'tend to your own business, and we'll 'tend to ours." We wore very happy when we read that one. The thread was indeed a very thin one that time because it was possible to do quite a number of things to "soup up" the system, any one of which would have occupied us for months to get back into a state of readability.

Tolice 513

I hardly need to give you a definition of communications intelligence, or COMINT, as we call it for short. No doubt Major Morrison has already dealt with it, so I will simply cite its three main objectives. First — to provide authentic information fer policy makers, to apprise them of the realities of the international situation, of the war making capabilities and vulnerabilities of foreign countries, and of the intentions of those sountries with respect to war. Second — to eliminate the element of surprise from an act of aggression by another country. Third — to provide unique information essential to the successful prosecution, and vital to a shortening of, the period of hostilities.

Now, the background of COMINT, which is based upon the science of cryptanalysis, has a long and very interesting history which is inextricably bound up with the history of cryptography. The two are but opposite faces

of the same coin, for progress in one inevitably leads to progress in the other. Hence, while my talk is to be devoted largely to cryptanalysis and COMINT, I will have to deal also, to a certain extent, with cryptography and communications security or COSSEC. Now, because of the secrety or closk of silence which officially surrounds the whole field of cryptology and especially cryptanalytics, it is obvious that authentic information with reference to the background and development of the science in foreign countries is quite sparse; and although after World War II we learned much regarding the accomplishments in this field of work by our enemies, security rules prevent my saying very much about how good or bad they were in comparison with us. I can only give a fairly good account of U.S. COMINI activities up to a certain point of time, and even then I will not be able to say very much about the U.S. Havy's COMINT activities, because I don't know very much about that background and prefer not to give any information which I can't document. In any case, I might say at this point that our relations with the Navy in the early days were such as to preclude my knowing very much about what they were doing, and vice versa. In the course of my talk I will give illustrations of cryptanalysis, some of which form part of my own experience. Modesty would dictate their omission, but because of . their possible interest I will use thom and will here and now make a general apology for the use of the personal pronoun.

Now may no have the first slide, please. Cryptography and cryptOut we won't have
analysis go back to the dam of the invention of writing, and here I
fine to go back quitethat for even the ghit that for it we won't had
show an instance of cipher in the Bible. In Jeresiah 25,26 occurs the
Houttan for the fine place of the Science.

(51) Was recognized for the grant support days of the Science.

And the carboar books on cryptography and or a tree factor from one
of the carboar books on cryptography.

empression "And the king of Shesbakh shall drink after them." Also in Jeremiah 51:h1: "How is Sheshakh taken !" Well, for many, many years that name "Sheghakh" remained a mystery. There was no such place. But then somebody discovered that if you write the twenty-two latters of the Hebrew alphabet in two rows, eleven and eleven, like this, you set up a substitution alphabet whereby you can replace the letters by those standing eposite them. For example, "Shin," is represented by "Beth" or vice versa, so that "Sheshakh," translates "Babel," or "Babylon." The vowels had to be supplied. Incidentally, mentioning the Bible, one might say that Daniel, who was the first psychoenalysty, The also the first oryptenalyst. I say paychoanalyst, because you reasaber how he interpreted Mebuchednezzar's dreams. In the Bible's om words, "Nebuchadnessar dreamed dreams, wherewith his spirit was troubled, and sleep brake from him." But when he woke up he just couldn't seen to remember them. One norming he called for his magicians, astrologists, and chaldean sorcers and asked them to interpret the dream he'd had during the night. They asked him: "That was the dream?" and he said, "Well, I don't remember it, but it's part of your job to find that out and then to interpret it." That was a pretty stiff assignment, and they failed to make good, which irked Hebuchadnesser no ond. Kings had a masty habit of chopping your head off in those days if you failed; so in this case it comes as no surprise to learn that Nebuchadnezzar passed the word along to destroy all the wise men of Babylon, including Daniel. Wall, when the King's guard came to get Daniel, Daniel asked that he be given a bit of them. Then, by some horus-popus, - the record simply says that the segret was revealed to Daniel in a night vision - Daniel was able to reconstruct the dress and then interpret it. Some years later, Nebuchadnezzar's son, Belchassar, was giving a feast, and during the course of the feast the fingers of a man's hand appeared on the wall behind the candlestick and wrote a secret sessage; Belshassar was very much upset and called for his soothsayers, chaldean sorcerers, magicians and so on, but they couldn't read the meassage - apparently they couldn't even read the cipher characters; Well, Daniel was called in and succeeded not only in reading the writing on the wall: "Meme, meme, takel, upharain," but also the meaning of the words. His interpretation was "Meme" - God hath numbered thy kingdom and finished it. "Takel" - Thom art weighed in the balances and found wanting. "Upharain," or rather "Peres," (apparently the chap who did the handwriting on the wall knew a thing or two about cryptography, because he used "wariante,") - Thy kingdom shall be divided and given to the Medes and Persians."

The next is an illustration of the earliest cipher device history records, a device which was called a <u>soytale</u>, used by the ancient

Lacedamonians or Greeks. They had a wooden cylinder of specific dimensione, around which they wrapped spirally a piece of parchaent; they then wrote the message across the edges of the parchaent, unwound it, and sent it to its destination, where the recipient would wind to parchaent around an identically-dimensioned cylinder, and thus bring together properly the bits of letters representing the message. This

edges of the parchaent, as I said before, and not assuom in this

diagram, incidentally, is not correct. The writing was done along the

picture. And, by the way, the baton which the European field sarshall still carries as one of the insignia of his high office derives from this very instrument.

Caesar, of course, is well known in history to have used cryptography - a very simple method, obviously, because all he did was to replace each letter by the one that was fourth from it in the alphabet. Ciesro was one of the inventors of what is now called shorthand. He had a slave by the name of Tiro who wrote for Cicero his records and so on, in shorthand or Tirronean notes, as they are called.

The beginnings of sodern cryptography are to be found in Venice. in the Papal states, about 1400. I show next an alphabet of that period which is interesting merely because it shows that in those early days they already had a recognition of the basic weakness of what we call single or monoalphabetic substitution. Solution of this type of cipher, as you all know, is accomplished by using data based upon frequencies. I don't have to go into that because all of you, at some time or other, have read "The Cold Bug," and understand that sort of analysis. But this slide shows that the early Italian cryptographers introduced a method of disturbing the normal frequencies, by having the high-frequency lettern represented by more than a single character. I will add that the earliest tract that the world possesses on the subject of oryptography, or for that matter, oryptanalysis, is that which was written in 1474 by a Meapolitan, whose name was Sicco Simonetta. He sets forth the principles and methods of solving ciphers, as simple ciphers no doubt, but he describes them in a very clear and concise form. The first book or extensive treatise on

REF ID:A66402

cryptography is that by a German abbot named Trithemius, who wrote his mommental work in 1531. He planned to write four volumes, but he quit with the third one because he purposely wrote so obscurely and made such funtastic claims that he got charged with being in league with the Devil. They burned his books, as a matter of fact.

(3.5)

We are going to jump a ways now to some examples from more recent history. This slide shows a cipher alphabet and system used by Mary. Queen of Scots, in the period 1545, or thereabouts. There was an Italian cryptographer whose name was Porta and who wrote a book, published in 1563, in which he showed certain types of alphabets that have come down in history and are known now as Porta's Alchabets. Here's an example of the Porta Table, showing one alphabet with key letters A or B, another alphabet with key letters C or D, and so on. I don't ment to go into exactly how those key letters are used, but it is sufficient to say that even to this day cryptograms using the Porta alphabets are occasionally encountered. Incidentally, Porta was quite a fellow. There are lots of people who refer to his book but have never read it. I took the trouble to have it translated to see just what he did say, and he was, in my opinion, the greatest of the old cryptographers. Incidentally, also he was the inventor of what we know as the camera obscura, the progenitor of our sodern cameras. I think also he was one of the earliest of cryptanalysts able to solve a system of keyed substitution, that is, where the key is changing consistently as the message undergoes encipherment. Porta's table was actually used in official correspondence. Here is a picture of a table that was found among the

state papers of Queen Elisabeth's time, used for communicating with the English Ambansador to Spain. It used Porta's alphabets.

(5)

The next slide I show is a picture of what cryptographers usually call the Vigenere Square or Vigenere Table; a set of twenty-six alphabets successively displaced one letter per row, with the plain-text letters at the top of the square and the key-letters at the side. The method of using the table is to agree upon a key word, which causes the equivalents of the plain-text letters to change according to the manner in which the key changes. Now, Vigenere also has an interest to as because although he is commonly credited with having invented that square, he really didn't and, what's more, never said he did. Here's a picture of it as it appears in his own book. It goes considerably beyond what the ordinary references say about his table, but I won't go into those differences because they're technical and perhaps of no great interest to you today.

The next cryptographer I wish to mention is a Franchman, Francois Vieta, an emminent mathematician, founder of modern algebra. In 1589 he became Councelor of Parliament at Tours and then Privy Counselor. While in that job he solved a Spanish cipher system using more than 500 characters, so that all the Spanish dispatches falling into French hands were easily read. Phillip II of Spain was so convinced of the safety of his cipher that when he found the French were aware of the contents of his letters to the Netherlands, he complained to the Pope that the French were using sorcery against him. Vieta was called on the carpet and made to emplain. Here is another example of another old official cipher. Here are

two

10

SECRET

(3.7)

the alphabets; and a sliding card, which could be shifted up and down, was used for changing the key, or as a means of changing the key. Here is another, called the "two-square cipher," or "two-alphabet cipher"; it involves coordinates: here is one complete alphabet and here is another one; the coordinates are used to represent the letters. That was actually used in Charles I's time, 1627, in communicating with

France and Flanders.

I went to jump come to the period of the American Revolution, in U.S. history. The systems used by the Americans and by the British were almost identical! In one case, in fact, they used the same code book! I have seen references to an American who seems to have been the Revolution's AFSA, for he was the cipher expert to Congress and it is claimed that he managed to decipher nearly all, of not all, of the British code messages intercepted by the Americans. The next chartshows a picture of a code or "syllabary," as we call it, used by Thomas Jefferson. This syllabery is constructed on the so-called two-part principle. This is a portion of the decoding section. You will note that the numerical groups are in consecutive order but their meanings are at random. They have no alphabetical order at all. It simply means that you have to have another section, the encoding section, in which the words are in alphabetical order, and their equivalents are in random order. This sort of system even today is in extensive use. Jefferson was an all-ground genius, and I shall have something to say about him and cryptography a little bit later on, I hope. Here's an interesting slide showing a picture of a letter which is known me Benedict Arnold, of tioner Colomial infamy. He even was willing to see that his commander in - chief, washingtone, was captured, by giving the British information 11 like thus.

6.4

2

Indecipherable Treasonable Cos Latter." It has never been deciphered. It reads, "I have bought a cos and calf from Gen. John Joseph Bullis," and so forth. The reason that it hasn't been deciphered is that there isn't enough of it to form the basis for a solution.

Ex.

4,7.

I am going to say a few words about Egyptian hieroglyphics for the reason that I think that that represents the next and a great landwark in the history of cryptography. About 1821 a Frenchman, Champolion, startled the world by beginning to publish translations of Egyptian hieroglyphics. This is a picture of the Rosetta Stone. It is a trilingual inscription: Egyptian hisroglyphics, followed by Egyptian script called "Demotic" and then Greek. All three texts were assumed to say the same thing, of course. It was by means of this tri-lingual inscription that the Egyptian hieroglyphic writing was finally solved, a feet which represented the successful solution to a cryptanalytic problem, the major part of which was linguistic in character, for the cryptanalytic part was relatively simple. In the hieroglyphics there are things that we call cartouches, that is, characters enclosed in a rectangle marked by a graven line. Here are some examples. This one was on an obelisk, and was suspected of representing the name Cleopatra. I suppose the reason for that assumption was the repitition here of two characters at a proper distance to represent the two A's of Cleopatra. By taking the various cartouches, writing them out carefully, studying them on the basis that this cartouche was Cleopatre, it turns out that by taking the characters in the cartouches, substituting their equivalent Roman letters and putting them in the proper places in other cartouches, bit by bit Champolion was

## REF ID: A66402

able to establish names other than Cleopatre, such as Ptolemy, Alexander, and so on. That's the way in which a start or initial break was made with respect to the Rosetta Stone, and Egyptian hieroglyphics were finally read. It was very fortunate that the early students of Egyptology didn't know that the Egyptians also used cryptography! Some of their writings are not only "plain-text hieroglyphics," but they also had "cryptographic hieroglyphics"! Here, for instance, is an example of substitution. That character in place of this one means "to speak." You see the finger pointing to the mouth, and so on.

Between the States," in U.S. history. Here is a picture of a cipher device used by the Confederate Army, captured at Vicksburg, one of our Museum treasures. The device in a cylinder covered with a sheet of paper bearing alphabets, the alphabets of Vigeneire table, in other words, a pointer that you could slide, and a thumb knob with which you could turn the cylinder according to the key latters.

There is one person I passed over in getting to the Civil War period.

Edgar Allan Poe, in 1842 or thereabouts, kindled an interest in cryptography by his famous story of "The Gold Bug," and by some articles on cryptography in newspapers and journals of the period.

Here is a picture of a message, authentic without question, which
was sent by President Lincoln to Gen. Burnside. It's very simple. It
reads this way, of course, and makes no sense; but if you read it backwards it makes excellent sense: "If I should be in a boat off Aquia
Creek at dark tomorrow, Wednesday evening, could you without inconvenience

(3)

meet as and pass an hour or two with me? (Signed) A. Lincolnes I think the President was kidding a bit.

9

(10)

This is a photograph of a page or two from the code book and cipher system used by the Federal Army. They had what is called "route ciphers," that is, a matrix with indications of route to be followed in inscribing and transcribing the words of the message. Here's how you write the message in: the first word, second, third, fourth, fifth, sixth and so forth; then you take them out according to another route. And here the thing is complicated by the use of arbitrary equivalents for the names of important people. "President of the U.S." is represented by "Adam" or "Asia." It had two equivalents, you see. Here are some of the names of famous or well-known officers of that period. I have with se today the complete set of cipher books used by the Federal Army during that period, and after my talk those of you who wish may come up and examine them, together with certain other exhibits. The next clide is a picture of a message sent to General Grant in one of those route ciphers. I shall not take time to read it.

There is an example of a type of secret writing employed by the French in the Franco-Prussian War. It consisted of code groups written out from a code book. You remember that in the Siege of Paris the French were completely cut off, so that messages had to be sent out by pigeon. The message was photographed down, and — this, I believe, was the first and earliest example of micro writing used for military purposes — the message was, as I said, photographed down and sent out by means of carrier pigeon. This is a copy of one of the examples.

14

SECRET

REF ID: A66402

2 2 2

214)

After the Civil War, or War Between the States, the use of cryptography in United States military affairs went into a decline for a long period of peace, and was broken only briefly by the Spanish-American War. In 1885 the War Department published a code called "Code to Insure Secrecy of Telegrams," based on a small commercial code, almost word for word. I have a copy of that with me and if you wish to examine it you'll get some idea of how naive we were in those days! In the Spanish-Assrican War there was very little use made of sound cryptography, for we used that code, which had no secrecy whatever; but then we must remember there was no such thing as radio in those days, either. In 1899 the Chief Signal Officer undertook the preparation of a suitable code. Economy was stressed - the Chief Signal Officer personally did all the work. In 1902 the "Cipher of the War Department" was published by the adjutant General. In 1906 a revision of that was published, and in 1915 a completely new code, the War Department Telegraph Code, was published. But, believe it or not, that code was printed by a commercial

house in Cleveland! When the U.S. Interest who W.W.I in April 1917 this Code was the and white ends the Armyfield — and the Buttish head to take in it breasth and a to the Borld War I period. With Herta's discovery of the to was the so-called Hertaian waves and Marcomi's practical demonstration of signalling by wireless, a new era in military communications was ushered in, and also a new era in cryptology. The first wide usage of wireless, or radio, as it soon case to be called, was in World War I, but developments in cryptography lagged a bit, as we shall see.

First, I will discuss the tactical use of cipher systems in World War.

I, because these were used in preference to code systems, which came later.

Here is a picture of a cipher system used by the Russians. You will note

(Ti:

SECRET Tansuberg

(13)

(13)

that it is nothing but the Vigeners principle all over again, using numbers instead of letters, for it represents only a case involving a set of 7 or 8 alphabets used repetitively, by a key number, for substitution. This was the deciphering table. The next slide is a picture of a front-line cipher system used by the French. It was a transposition system, the columns being here transcribed according to the columner key; in addition, certain disturbing elements came into the method by taking off the letters in diagonals. And here is a picture of the system used by the Italian army in World War I. Again. it is only a variation of the old Vigenere system. Here is a system used by the Gersans, invented by them, or, I should say, it was a combination of two methods put together in a very clever way. We called it the ADFOVX ciphor because the cipher text consisted exclusively of those letters. An alphabet in here, arranged according to some prearranged plan, with the coordinates ADFUVX; the letters of the message were then replaced by pairs of coordinates; for example, the letter R is represented by AG, and so forth. Then a meserical key, developed from a key word, is written over the Xis, A's and so forth, and the letters are then taken out in columns according to the key order. That system was a brend new thing in militory cryptogramby and caused no end of headaches for the Allied cryptanalysts until it was discovered just how the solution could be achieved. The solution was not a general solution but depended upon special cases, but these happened so often that we could bank on them occurring. That cipher system was used by the German high command and consequently someone soon discovered that

REF ID:A66402

if you made a chart based upon the number of ADFOVX messages intercepted, why you could discover certain things about the tactical situation and, more important, you could, with some degree of assurance, predict what might happen. This is a chart which we got up in the AEF based upon the ADFOVX intercept. This, gentlemen, is the first illustration that I know of in history of one of the basic principles of traffic analysis, and traffic intelligence. The next slide gives a picture of the sort of "communiques" we issued, "Bulletins" that we put out when the ADFOVX messages were read. Here is one of a set of messages, dated November 20, 1918; of course the war was over, but this gives very important information about the withdrawal of Mackensen's army into Roumania. There is the German text and there is the translation, an interesting and authentic message.

For tactical messages the Aritish and Americans in World War I used a method known as the Playfair cipher, invented allegedly by Lord Lyon Playfair, but he didn't invent it - Sir Charles Wheatstone invented it. By-the-way, Wheatstone, who is credited with inventing the electrical bridge that is known by his name, didn't invent that bridge - a chap named Christy really did. The method of Playfair encipherment is to have a square 5 x 5, in which you start in with a key word, then the rest of the unused letters of the alphabet. (I and J are treated as the same letter). If you want to encipher "at" the equivalent is "vr", by diagonals, and so on. There is an example of how a message is enciphered. In those days, 191h, that was regarded as pretty hot stuff. In fact, an officer of the American Army (later he became Chief Signal Officer, Major General

(15

(213)

116

Manborgne) wrote a little treatise, published in 1914, in which he dealt with this Playfair cipher system. The title of his work is "An Advanced Problem in Cryptography." Today, our most elementary students are given things of that sort to solve after a few lessons.

The British Army proposed a cipher device in World War I. They had manufactured a great many of them and distributed thousands; they proposed to the French and the Americans that they use the same thing for tactical communications, but it was never put to use for reasons that I hope to tell you later.

Now. I'd like to say a few words about codes and code systems used in World War I. I think you all know that a code system is simply a sort of dictionary in which the words, phrases and sentences are representable by arbitrary groups of letters or figures. Here is a page from a commercial telegraph or commercial cable company's codebook, which they offer to their customers. You'll notice that each of these code groups differs from every other code group by at least two letters. We call that "the two-letter differential." The reason for having such a differential is that errors are sometimes made in transmission, but the likelihood of making two errors in the same group is not nearly as great as making a single error. The 2-letter differential affords methods of readily correcting a group if it has a single error in it; with a bit more trouble 2-letter errors can also be corrected. Now, code books and codes are compiled to be suited to general or specific kinds of business. They are generalized, like a general trade or shipping code, or a code for the automative industry,

and so on; but they may also be highly specialized in character. The next slide shows a highly specialized code. You know, there are certain people who believe firmly and implicitly in the power of healing by suggestion and what not, and here is a picture of a code book put out by a gentleman who was a professional AM in that field. You'll notice ting the purpose of it was, of course, to be able to receive treatment from or by your can prectitioner no matter where you went. Thus, if you going a trip and want to consult your practitioner, you can send him a message and tell him what you think you are suffering from. Of course, you think you are suffering from this, that or the other thing. The code is in English and French, and you would simply represent your illness, or alleged illness, by a code group. Now, note that the gentleman who got up this code was pretty well versed in the intricacies of code and communications difficulties, because these code groups differ by at least three letters each; the reason, of course, is that it would be a pretty serious thing if you sent a message saying that you think you are suffering from cours, but the group is garbled in transmission so that you get the treatment for convolsions. That would be pretty tough!

Prior to World War I the use of code books for tactical purposes
was thought to be impracticable, largely because of the difficulties of
compiling, reproducing, distributing and pretenting the books. I don't
think they thought too much about the possibilities of solving code.
Early in 1916 the Germans began to use field codes, and the Allies soon
followed suit. I had some slides to show you pictures of pages of the
code books of the various belligerants, but I will emit then and say

1022

that I also have brought establite of such books as were actually used
for the purpose. Those who would like to see what they were like are
welcome to come up after this talk and examine them. The only slide that
I will show is one that will give you a picture of the American Army's
inadequacy in Norld War I for each communications. This is authentic I didn't make it up - I found it in the records. It's a code gotten
out by the 52nd Infantry Brigade, dated 17 April 1918, and it is what
we called "the baseball code." If you wanted to say "killed," you said
"struck out"; "wounded" was represented by "hit by pitched ball," and
so forth - very elementary. But after a late Mart the Att Fledicks way
in faution, but full codes way magnetally.
Now I am coming to a very interesting example of the use of ciphers

راتق

251

by German agents in the World War I period. Here is a cipher message which was found on a German spy in the United States soon after he crossed the Mexican border into Texas. After some weeks it was deciphered by G-2's code-solving organization in Washington, MI-8, as it was called. Here is the deciphered German text, and this is what it said: "To The Imperial Consular officials of the Republic of Mexico. Strictly Secret; The bearer of this is a subject of the Empire who travels as a Russian under the name of Pablo Waberski. He is a German agent." And so forth. The Gourt sentenced him to be shot; President Wilson commuted it to life imprisonment; and he was out of the pokey after only one year!

Here is a message which is probably the most famous message in published cryptanalytic history to date. This is the message which brought the United States into World War I, on the side of the British.

In 1915-16 it was very much catch-es-catch-can as to which side the Americans were going to join. Our British friends, later our allies. did certain things that we didn't like, and there was a good deal of talk about their nefarious behavior. But this message, solved by the British, brought us in on their side. It was the straw that broke the camel's back. It is known as "the Zimmermann telegram." It want to the German legation in Mexico City from Count Von Bernstorff, the German ambassador in Washington. The method of solution I won't go into. Their eleverness in the handling of the case is a good illustration of how astute, diplomatically, our British friends are, for, as I have already said, it resulted in bringing us into the War on their side. Here is the translation of the thing. It was important because the message said the Germans were going to resume unrestricted submarine warfare and this part, here, dealing with a deal with Mexico, was the straw that broke the camal's back. People in the Middle West were very lukeward toward the idea of our getting into the Har - on either side - but when the Germans began talking about returning to Mexico, Texas, New Mexico and Arizona, that was something else again. So, we got into the war within a couple of weeks after the British gave us and established the authenticity of the translation of "the Zimmermann telegram."

(30) The state of the state of

Here is another message solved in World War I by the British and made available to our authorities in Washington: a sabotage message talking about who were reliable saboteurs and what they should do. That message figured in a long, long trial before the German-American Mixed Claims

\_\_\_\_\_

Commission, in which the Germans were charged with certain acts of sabotage, notably the Kingland fire and the Black Tom emplosion in New Jersey. Most of you are too young to remember those incidents. The trial resulted in a decision in favor of the United States claimants, who were awarded some \$40,000,000. Here is a message, in secret ink, that figured in the Black Tom Case: a page from the Eluchook Magazine, on which there was a message written in invisible ink, a mathod we run into occasionally even in modern warfare.

Now I come to a case in which I was involved. In 1916-17 the Gersans financed a large number of Hindus in their attempts to stir up a rebellion in India, the idea being to cause so much trouble in India that the British would be forced to withdraw troops from the Western front to quell disturbances in India. These Hindus were negotiating for the ourchase of arms and ammunition in the United States and sending them over to India. Since the U.S. was neutral, it was against our own laws to permit such undertakings against a friendly nation. So the business had to be conducted secretly and that is how cryptograms entered into the picture. Here is one page of a long, seven or eight-page letter that was intercepted between the top Hindu agent in the United States and his chief in Switzerland. The letter consisted of groups of figures. in which were interspersed some plain-text words. I recognized pretty quickly that the letters of the secretificant had been replaced by numbers which indicated specific letters in a book. Each group of numbers represented the page number, the line number, and the position number in the line of the letter. All I needed was the book, but unfortunately the Hindu failed to tell me what the book was, so I had to go ahead and

try to solve the message without it. It was solved, and I'll show you very briefly the method. As I said, there were words, plain-text words. interspersed throughout the eigher text, and I would make a guess at what the numerical group before or after a plain-text word represented. Here, for example: "Formed scaething, with scaething," I assumed that this first "something" would be the word "committee," and that meant that on page 65, the fourth line, the second letter in the line was a C; the third to be O; the fourth M; the fifth another M, but the sixth letter in that line was not indicated. Instead, the next group jumped to another page, from which the letters I, T, T, and so on were taken. Well, by substituting some of these guesses in their proper positions and making tabulations of this sort. I assumed that the first five letters of this word "committee" came from the word "communication" on page 65, line h; the next three, from a word having "TTE" in it, such as "attention"; but the last letter, E,/from another page altogether and I could only add nore data before adding any guess as to must the word on page 72, line 2, might be. By working back and forth, building up the various words on various pages of the book, then building up the words of the message - one helped the other - I finally got certain clues as to the sort of book involved - that it was a book dealing with the history of German political philosphy, economy, or history. I hunted and hunted and hunted for that book. I finally found it, all right. It was Price Collier's Germany and the Germans. This message figured in a long-drawn out trial in San Francisco, where there were about a hundred and five Hindus on trial simultaneously. One of the Hindus turned State's evidence and got

REF ID: A66402

-SECRET

himself in bad with the others. They were searched every day before they came into the court, but one day, the day after I testified, one Hindus managed to secrete a gum in his clothes and during the midst of the proceedings shot the Hindu who had turned State's evidence, where-upon the United States marshall, a great hig fellow, six feet four, standing in the back of the court, drew his meapon and shot the first Hindu dead. They were both dead right there, within two or three seconds. That's the way that trial ended up, dramatically.

seemed in the days of 1921. I was government witness in that case, having solved the messages which disclosed some of the facts that lead to Mr. Fall's going to prison. He was Secretary of the Interior, if you recall. I think he died only recently.

The run runners in those lamentable days of prohibition, used some very good codes and ciphers. Here is a particular case where a message was enciphered by taking code groups out of one book, transferring the code numbers for those groups into another book and then adding a constant value to those numbers, finding the letter-group equivalents of the final numbers, then enciphering those letter groups! This was such a message. All I had to do was to find the two code books, the additive, and the cipher alphabet. Lightwhing struck one night and the job was completed in a few hours.

There were some interesting things, working on the job in peacetime, when we would get messages from various government agencies to solve.

₹~

Here is one that came to the White House and was ment to us by the Secret Service. It was addressed to the President and had this dagger stuck in after this message. If you read it backwards and take alternate letters it asked President Roosevelt: "Did you ever bite a lamon?"

Now I am going to jump to the question of cipher devices, because they represent the modern trend. I've already mentioned to you the point about the invention and introduction into wide usage of radio, and their effects upon military matters, especially upon cryptology. Traffic in large quantities became available for interception and study, and hence improvement in cryptography had to come. It came slowly but surely. In connection with theoretical advances in cryptographic methods came inventions of cryptographic devices and machines. A brief history of there will therefore be useful. That is a picture of the earliest cryptographic device on record, except for the scytale. This is taken from a book by an Italian named Alberti, published in 1470, and is just a pair of alphabets, one revolving concentrically upon the other, so that you could change the relationship of the two alphabets. This wheel is represented also in the Porta book, and, by the way, I have with me today a copy of the original edition of Porta, with the cipher wheels in place and in working order. This was published in 1563. They didn't have any children in those days, obviously, or otherwise these things wouldn't be here, and All and the second of the seco in good working order i

I know it takes a long time to get a potent through the patent office, AST but Alberti's device was finally patented in 1865, the inventor happening to be the then Chief Signal Officer of the Army, Major Albert J. Myer.

25

45

44.1

45,4 Believe-it-or-not; the same thing was used by the Signal Corps of the United States Army as a new invention perhaps, in the period 1910 to 1918. There is a more recent invention of the same thing. The patent office doesn't have good access to literature on the subject of cryptology, so every ence in a while a thing that is as old as the hills gets through the patent office. Now we come to an interesting device. I mentioned a little while ago that the British proposed a cipher device for use on the Western Front in World War I, and a little bit of history 48 of that development is interesting. Here is a picture of a device invented by Sir Charles Wheatstone, the essinent British mathematician, physicist and electrical engineer. He was also a cryptographer of some stature. The principle of the Wheatstone cipher wheel is just a little different from that of Alberti's or the Signal Corps. This one has an alphabet of 27 characters and an imper alphabet of 26, with an eccentric motion influenced by the letters that you were actually going to encipher. With this hand, you see, you go around this way, and, for example, if the letter H is represented by Es on the next revolution H is represented by the next letter, which happens to be a V for victor. Now the British took that bagic invention, and souped it up a bit. Perhaps you noticed that on the first slide the outer alphabet consisted of the letters in normal English order, on the inner alphabet the letters were in mixed order. What they did was to add the idea of a mixed alphabet on the outside or suter alphabet. They changed the form of the device itself, but the cryptographic principle

49

is identical. Here it is. They had a great many of these manufactured.

I was at that time, in the Antenn of 1917, working at the Riverbank

Laboratories. This thing had been approved by the British, the French and the American cryptographers in Europe. It was sent to Washington, approved there by the MI-6 people, but somebody there said, "Well, let's see what this fellow out in Chicago thinks about it. So they sent us a not of five very short test messages enciphered by this device. All I knew was that a device based upon Wheatstone principles was probably involved. Hy employer came to me and gave me these five massages, each message only 35 or so letters long. He said, "I want you to solve this thing.\* I said. "But I can't solve anything as short as this. It's abourd and unfair. I don't want any part of such a test. Besides, I have other fish to fry." He said, "Young man, on the last day of each month you get a little green piece of paper with my name in the lower right hand corner. If you would like to continue receiving those pieces of paper, you will start work on this right away." I said, "Yes, Sir!" Well, by hoous pogus which I won't go into, I succeeded in reconstructing what I thought was the basis for the mixing of these letters in here, the letters of the igner alphabet. The word on which it was based second to be the word "cipher," and I thought, "Well, so far so good, but unfortunately there is no way of reconstructing the outer alphabet by analysis." At that time I hadn't invented the principle of doing so, although about a dozen years later I did so. But in 1917 there was nothing to do but try to guess what the keyword for the outer alphabet might be, by trial and error, and I made this assumption: If a fellow was foolish enough to use a word like "clipher" as the basis for mixing one alphabet, he'd be likely to use an agreedated word as the basis for mixing the other. I tried every ward

associated in my mind with the word "gipher," one after the other, and it took minutes to test each guess. I thought of words like "alphabet. secret, substitution, Wheatstone, and so on. Finally, I exhausted my efforts. Mrs. Friedman, who was my right hand man at the time. was sitting in another part of the room, and I said, "Risabeth, will you stop what you're doing and do something for me?" She said, "What do you want us to do?" I said, "Make yourself comfortable, I am going to say a word to you, and I want you to come back at me with the first word that pope into your head." The pade a page in two with her lipstick and said, "Shoot," I said, "Cipher," She said, "Machine," That was it! In about ten minutes we had reconstructed the outer alphabet and solved the messages. The first message said: "This cipher is absolutely indecipherable." We telegraphed the solution to Washington, word got to London, and they had to kill the project. When I got to the AEF in France I wasn't very well liked by our British friends. That Wheatstone principle is attributed to Sir Charles, but not long ago by sheer accident I came across this device: it's in our maseum now and was made by a Major Decius Wadsworth, U.S. Army. Wadsworth was aide to General Wilkinson. of Revolutionary fame, and he later became Chief of Ordnance. How he became interested in ciphers I don't know, but he certainly made this device. It beers on it - this is a very poor picture - the date 1817, while 1670 Thestatone conceived his device and described it in 1870. Hence, credit for the invention of the so-called Mestatone principle belongs not to an Biglishman, but so an American, who ant-aposted Wheatstone by over hulf a catu

49.1

I come now to a cipher device allegedly invented by a Frenchman, a Commandant Baseries, and called the "cipher cylinder." The Baseries device

49.4

160

50.1

consists of a shaft on which are nounted 20 discs which can be arranged in keying order, each disc bearing an identifying number and having a different alphabet on it. Having set up the discs in key order, you line up the letters of your plain text message thus: "Je suis Indechiffrable" ("I am indecipherable") is what it says on this line: and for your cipher text you can take any one of the other horizontal lines of cipher letters. This looks like a system based upon an excellent principle, but it is quite readily solvable these days - if you have the device. The principle, however, was not invented by Pageries; it was invented by our own Thomas Jefferson, and here is his description of the device which he called "the Mheel Cypher," using exactly the same principle. I had an interesting time disging up the facts in connection with an article I was asked to write for the definitive edition of Jafferson's writings now being published at Princeton, In 1915-16 a United States Army officer by the name of Parker Hitt independently invented that game principle again, this time not in the form of discs, but sliding strips, you see; this is a picture of his original model. Mrs. Hitt came to Riverbank, where I was then educating syself in oryptography, and she brought along her husband's invention, saying it was pretty hot stuff. She put up a challenge message on the device, which I solved by home pocus, you might say, like this! I thought to myself, "Well, this lady, Mrs. Hitt, is beautiful and charming, and so forth, but she doesn't know much about cryptography. What kind of a key would she be likely to use for mixing up the order of the strips? Well, she might use the key 'Riverbank Laboratories. \*\*

29

9

50.2

That was it! In 1918 that same principle was adopted by the United States army Signal Corpe; there it is, the M-Ri device. This, as you see, uses 25 discs with differently mixed alphabets; you can put them on in any key order you please, — exactly the same principle as Jefferson's or Basaries' or Hitt's device employed. We used Cipher Device M-Ri for quite a member of years after World War I with some success. The Many, the Marine Corps, and the Coast Chard also used it. By adopting Hitt's aliding strip form, which lends itself better to changing the mixed alphabets frequently, we got greater security in a device we called "the

50.12

56

10.4

This, gentlemen, is a picture of the very first SICTOT or one-time tape anyptographic transmission machine, produced by the ATAT Company in 1918, too late to be used in World War I. The principle is: here you perforate a tape bearing your plain-text message, here you have a previously-

prepared keying tape passing through a transmitter, here is enother keying tape passing through another transmitter; these tapes are different and in the form of loops of different dismeters. Suppose this one is a thousand characters in length and the other 999. If you start them out at initial given points, according indicators, those two points won't come together again until you have enciphered 999,000 characters; A pretty good principle, but, again, on a challenge, - this was after I came back from the AEF, was demobilized and them went back to Chicago to the Riverbank Laboratories — on a challenge, I solved a set of messages in the system, without having the aschine or the key tapes. This was supposed to be absolutely indecipherable;

Ordered so in writing in a letter signed by the Director of Hilltony

### REFEED A66402

Intelligence, but I was able to solve the thing, as I have just said, without having the tapes, without knowing how long they were, or the machine. It was a long and interesting solution, but I haven't the time to go into it.

710)

This is a picture of a new type of cryptographic machine. A gentleman by the name of Hebern out in California came forth in about 1922-23 with a keyboard, a rotor which acts as a switching comutator really. The current from the keyboard depressions enters at this side (a fixed comutator), goes through the wheel here, exits at this fixed computator, and then to the light-bank or typewriter. Now, this machine had only one rotor. In about three or four years, after collaboration with the Navy, he came out with a five-wheel machine, five rotors, you see, and these are the types of rotors that he used, which gave pretty high security. The Mayy was about to adopt these things. They were about to place a contract for \$75,000.00 with Hebern. How that hit me when the chief of the Mavy Code and Signal Section, Lieutenent Strubel now Admiral Strubel in charge of the 8th Fleet in the waters around Permoga - told se what the Navy had in the way of cash for cipher machines! We in the Army didn't even have a dollar for that sort of thing at that time! Well, Strubel asked me: "What about it?" I said, "I'll study it." I studied the matter for about six weeks before I had a really good idea. Then I went to Strubel and said, "I think I can solve messages." He said, "You'll have to show ma." I said, "All right, I accept your challenge." He said, "OE. What do you want?" I said, "I want ten sessages set up on your machine." He gave me the ten messages, and I solved the thing.

It was a curious thing that happened to me one evening as I was getting dressed to go out. I'd been working at the problem, of course. and it took weeks of making distributions and finding my way arounds I had one assistant at the time - he was a veteran, an exprise fighter, with grossed-eyes, cauliflower ears and all, and he wasn't much help, except in typing. I had reduced a problem involving millions and millions of alphabets to a place where I had one line of 26 letters reduced to a certain form. If I could solve that one line I would have a start. Well, I went home that evening I mentioned, much preoccupied. I had a clear picture in my mind of this one line, but all I know was that certain letters were the same, certain ones different - and, of course. I kept in mind the specific positions of these letters. For instance, the first six letters were all different, but the 3d. 7th. 14th, 19th and 25th were identical; the 4th, 21st and 26th were identical, and so on. Well, as I said before, while getting dressed to go out to a party that night, fiddling with my black bow tie, all of a swiden it came to me in a single flash, like lightning ! The phrase that would exactly fit the positions of the repeated and the different letters was "President of the United States." That was it! The next day I came in and verified the assumption. In a few days I handed the Navy a solution; they killed the order. The Reborn firm went to pieces; Reborn, the inventor and president of the firm, wound up in San Quentin for a couple of years because he ran afoul of California's "blue-sky laws." You see, the Hebern Company's stock had skyrocksted on the hot tip that a Mayy order was coming through; and when the Havy order didn't come through as anticipated, the stock dropped to about \$2,00 a share. Hebern picked up some of the \$2,00

(165)

172.19

stuff, went to a different part of the state, and sold it for \$10,00, The California authorities didn't like that, so they put him in the hoomegou-

54

55

one of the This is a picture of the first cipher machine; invented and built in the senty 200 and in Europe, called the Enigns. It was sold on the commercial market until the Masia came into power. Here are the rotors, you seep four of them here, a keyboard and the light bank. You press the keyboard, the rotors step, and the lamps light up. You position these rotors according to presgranged keying instructions. Now, also in Europe a bit later there were other inventors. Here is a machine called the Eryha, which was considered to be a very complicated and difficult thing - nobedy could solve it. Here is a German professor who put out a treatise on the indecipherability of the thing, showing how many permutations and combinations there were. Everybody in the world could be provided with a machine and a different key, there were so many permutations and combinations available. Well, gentlemen, merely the number of persutations and combinations that a given cipher system affords. like "the birds that sing in the spring," have nothing to do with the case, or at least very little. It all depends upon the nature of those permutations and combinations, that it, what they are basically in the cryptographic sense. For instance, take the principle of monoalphabetic substitution. the principle Poe used in "The Gold Bug." Theoretically, with a 26-letter alphabet you can sales 26! elphar alphabets. Now 26! is a large number: hoj,251;161;126;165,635,581;000;000, that is, four hundred and three quadrillions, two hundred ninety-one thousand four hundred and sixty-one

trillions, one hundred twenty-six thousand six hundred and five billions, six hundred thirty-five thousand five hundred and eighty-four millions. Quite a large number. So, if you were to try to solve a cipher such as that in "The Gold Bug" and were to go at it simply by trying all those quadrillions of permutations of the alphabet, you'd need lots of time and manpewer. Because it has been calculated that merely to write down those permutations it would take a thousand million men working a thousand million years to do the major part of the job - not all of it - and the scroll would reach from Earth far beyond the planet Hercury!

Tet, any of you can solve "The Gold Bug" cipher in a few minutes, despite the wast number of permutations that a 26-letter alphabet affords.

Here is a picture of a Swedish machine of about the same period:

58.1

59.

tane.

65

a keyboard; a light bank; and a set of rotors. The rotors are of a hit different type in this case. Of course, the light-bank type of machine was slow. You had to sit down and copy by hand and so on; so the inventor of this machine hooked it up with an electric Remington type-writer, and that was the first model of a printing cipher machine. He later modified it so as to have the printing machanism self-contained in the cryptograph, and that's a picture of the machine from the outside; and there is a picture of the internal workings. There is the keyboard, Here are the switching comutators, with pins which are put in end out of effective positions, like on our Converter M-209. Those pins drive a cortain lever, here, which drives the switching comutators, which are in here; you can also switch the effects of the comutators by means of these plugs. Here is the printing machanism. This style you'll recognise as being very similar to that in Convertor M-209. The text is printed on a

3 SECRET

60 ...

Years ago, of course, considerable thought began to be devoted to the encipherment of teletype communications. Asids from that 1918-19 A.T. & T. Company machine that I showed you a few minutes ago, this was the first of the teletype cipher attackments developed for security purposes. It was an invention of Colonel Parket Hitt, who retared from the army about 1925 and joined the International Telephone and Telegraph Company, where he devoted himself for two or three years to producing this machine. There's the internal mechanism. It had keying wheels which affected the five bands representing the teletype characters. These mbeels were of differential disasters. This one had 101 points, this one 99, this one 97, and so on, down, so that it had an entremely long period; but the length of the period, again, like "the bards that sing in the spring," has little to do with the case. The machine was put into test usage in the State Department, which called upon the War Department to make a security evaluation. I was assigned to the job, and had an interesting time with this. The State Department put up a series of messages. They were stamped in at a certain hour, about 10:00 ofclock in the morning; about 10:30, Mr. Salmon, the chief of the State Department communications, called me and said. "The machine is out of order. Maybe you can fix it." I said, "I'll be up there in a few minutes." I slipped a piece of paper in my pocket, and hustled over to the State Department, then in the old State, War, and Many Building. Upon arrival, Salmon was apologetic. "I'm sorry," he said, "I tried to catch you, but you had already left. It's working again, so I won't trouble you." I said, "By the way, I have a question to ask about those messages. He immediately got enspictous and asked, "What do you want to know?" And I said,

"Have you got the plain texts to those messages here?" He drew himself amy from me and said, "We-el, yes," I said, "Where are they?" He said, \*In that safe over there." I said, "Well, I'll sit here. You go over to the safe and dig out message No. 7. I want to ask a question about it." Your reluctantly he got up, opened the safe, pulled out message No. 7. and, with his back to me, the massage being held close to his vest, said, "What is it you want to know?" I pulled out my piece of paper, and I said, "Well, does it say ----?" and I read him the whole message. He almost sat down on the floor in astonishment. That was only 35 minutes or so after it had been received. The ITT Company burned its fingers on this development, gave up the investment and never tried again. I've told you about the ATAT Company studying and inventing cipher machines, and the IT&T Company; the Automatic Klectric Company of Chicago, and the IBM Company also tried their hands at it and failed, The basic reason for those failures is that without first-class cryptanalytic guidance nobody can invent a cryptographic machine that is going to stand up under organised attack by cryptenalysts with the proper "longer hour." But U.S. Army developed a successful crypto-attacking for telephone, in 1943. This is Converter M-209, which we adopted; it was a Swedish invention and is protty good. It was the only thing we came across in 1960 suitable

178 180 10.1

70,2

This is Converter M-209, which we adopted; it was a Swedish invention and is pretty good. It was the only thing we came across in 1940 suitable for our use in the field. Here are keying wheels. Here is a berrel of movable staves, which are affected by the keying wheels; the staves, as they move to the left, and in number from 0 to 25, affect a print wheel, and there is the tape. A very neat gadget but a bit slow and not too secure when you have two or more messages in the same metting.

10:3 = The efforts of two GI.s in Haly.

Conventer Mattack & SECRET

1739

1 M-134 C (Sigaba/ECM)

Now, the rest of the time I would like to devote to a brief discussion of oryptanalytic gadgetry. This, to my knowledge, is a picture of the first cryptanalytic aid, something I got up at Riverbank way back in 1916, I think it was: a pair of glass plates guides or grooves in which alphabet strips could be slid up and down in order to align letters and study them, for various purposes. I don't remember now why I put down on it "The U. S. War College." I had no relations with them, but it was nice to hand them a present, so I did that. I made those strips with my own hands. This was a wheel with rubber letters that I could arrange in any order I pleased to make up

Now, from that early start have come a great many very interesting developments. Here is a picture of a memo dated October 30, 1934, which I sent to Captain King and Major Akin, now Chief Signal Officer, and in which I made some remarks. You can see evidences of tears or maybe drops of blood on this thing. I was asking for a little bit of money to get please do your utmost to put this across for me. If you do, we can really begin to do worthwhile cryptanalytic work." 12 Well, the plea was successful - we got it. Here's a picture of part to the contract, you see, dated the 12th of November. It took only a month. And here is what we were getting, and see these prices. When I think of the millions of dollars which the Army's Signal Intelligence Service spent during World War II on this sort of thing, I am amazed that from such lowly beginnings should have come that great establishment of IPM apparatus. This is a room, just one wing of several in our headquarters during the war, with tabelating markines, kere, just one after the

alphabets. There's another view of the thing, and here's a whole bunch

of them put together, for whatever purposes necessary.

134

war, with tabulating machines, here, just one after the other IRI
machines, either stendard or modified for special jobs.

Cryptographics or a

You know the picture the average person has of a cryptanalyst. Here's a protuce - an old me - of a practical Cryptograph He's a long-bair. He wears thick spectacles, has long whishers with crumbs in them and so ons he goes into a hukile with himself and pretty soon he comes up with an answer. Well, that's far from the picture these days. Cryptanalysis and communications intelligence is "big business" now, and I want to say a word or two about that asvent of the subject. Cryptanelysis of modern systems has been facilitated. if not made possible, by the use and application of special cryptenalytic aids, including the use of high speed machinery of the type plotured here. Some are standard machines, but mostly we devise and use modifications of those machines. Here importantly we have recently gone into the invention, development, and production of electronics cryptanalytic gadgetry. At this point I must take a few moments to clarify the picture and in simple language tell you what such gadgets do for us. As I said before, the number of persutations and combinations afforded by a cryptosystem per se isn't too significant. It's what they are basically from the standpoint of their nature cryptographically speaking. In modern cryptenslysis what you are up against are complex dryptogratems which usually involve, for their solution, the making of a great multiplicity of hypotheses each of which must be tested out, one after the other, until you find the correct one. The job of the cryptanalyst is to devise short outs for testing the hypotheses, short outs often based upon the use of statistics relative to frequencies. Once

having devised the proper test or tests for each hypothesis, or for several concurrent hypotheses, husan labor can be set to work making the millions of tests in order to find the correct hypothesis or to mest out the vest sajority of incorrect ones. When the test is complipated, or lengthy, it is obvious that you'd have to have, as we used to say, factorial n Chinamen to do the job, or else the job would take cons. But it is our experience that every test which can be made by hand can be mechanized, and it is further our experience that in most cases it is practicable to build machines which will make the tests. I don't have to tell you that machines don't tire as rapidly as humans, they don't need much glosp, or time out for meals, or for recreation or for such things as shopping, love-making, etc. -- in short, the care and feeding sof machines is a relatively much more simple matter than the "care and feeding of human beings. So, we have cryptanalysts who devise the tests; then we have cryptanalytic engineers who mechanize the tests, and devise, invent, develops and produce the machines to perform the tests at high speed: then we have maintenance engineers who keep the machines in good working order; then we have cryptanalytic assistants who examine the output of the machines, and who are usually able to take the correct hypothesis or few correct ones and go on with them to the final stage where a key is recovered; then we may have other sachines which apply the recovered keys to specific messages and produce the plain texts from them. But in all these steps, let me emphasize, the machines only perform, at a high rate of speed, processes which the human brain and hand can perform but only at a much slower rate - these machines don't, they can't, replace the thinking processes involved in exyptensivals.

- STERET

145

Now, I want to show you what some of these machines look like.

Here is a highly-specialised machine for deciphering messages; we call

it an "enalog" because although it does what the enemy's cryptosystem

does, any resemblance between it and the enemy's machine is purely

coincidental. To emplain, I'll say this: In a cryptenalytic processing

center, we try to duplicate with a few people what thousands of people

on the enemy side are doing, for it takes thousands of soldiers, to

encipher and decipher the messages of the many beadquarters involved in the process with these messages, or most of them are intercepted, they all flow into one place, and you can only have a certain number of people to process them. If you have the key or keys, then it becomes a problem of production-line deciphering; so we devise special machines to decipher the messages. As I said before, the machine may not have any resemblance whatsoever to the enemy's cryptographic machine, but it deplicates that their machine does, and does so at a high rate of speed.

194

Here's a picture of such a device. In this next clide you see a tabulator, a standard tabulator with a special attachment devised by our own engineers susceptible of what we call doing "brute force" operations, where you are trying to solve a thing on the basis of repetitions which are few and

for solving cortain type of messages which never happened

عربه ا

137

scattered over a large volume of messages. Well, if you've got millions and millions of letters, the location of those repetitions is a pretty laborious thing if you have to do it by hand, so we speed the search up. A machine of this kind will locate those repetitions in, say, one-tentious and the time that it would take to do it by hand. Here is a specialised machine, egain a tebulator, with an attachment, here, that is

used for passing the text of one message against the test of another message in order to find certain similarities, or perhaps differences, or maybe homologies, and it does it automatically. These relays are set up according to certain circuitry; you start the machine, and low and behold, it produces a printed record of the message repetitious or what not.

140

the machine.

13 8

Here is a machine which I personally call "Rodin." Rodin was the great French sculptor who sculpted a piece of engineering known as "The Thinker." This machine almost thinks. That it does is this: you set up, or give it, or feed into it, a certain number of hypotheses and you tell it, "Now, you examine these hypotheses, and towns which will answer all the following conditions." The machine takes the first hypotheses, let's say, examines that, and if it comes to a centre-diction it says, "Hell, that's no good; I'll go back and take up the next one." And so on. It tests the hypotheses, one after the other, at a high rate of speed, at electronic speed. That's only one small section of

Well, we've got left here a few minutes in which I should say something about the current employment or manner of employment of communications intelligence. I've devoted two hours to talking about the background and development and haven't said very much about the manner of its employment. Well, we could discuss that under various headings, but it is obvious from the disclosures of the Congressional Pearl Harbor Committee that the manner of its employment in shortening World War II must have been very efficacious.

I wish I had the time to read you the whole of the Marshall-Desey

Chamberlin Statement 11

Phurchill on hunty

SECRET

REF ID: A66402

## -SECRET-

correspondence that the article in Time was based upon, but I think that just a brief extract will be sufficient to give you a pretty good idea of the contribution CCMINT made toward our winning World War II. These are all in that correspondence, which was practically broadcast to all the chanceries and war offices of the world when it was disclosed during the Congressional hearings. General Marshall, you'll remember, in his letter to Governor Dewey, sent during the hot political campaign of 19hh, was asking the Governor not to use certain information Dewey got by surreptitious channels. Here are some excellent illustrations of the manner of employment of CCMINT:

"Now the point to the present dilemma is that we have gone ahead with this business of deciphering their codes until we possess other codes, German as well as Japanese, but our main basis of information regarding Hitler's intentions in Europe is obtained from Baron Oshima's messages from Berlin reporting his interviews with Hitler and other officials to the Japanese Government. These are still in the codes involved in the Pearl Harbor events.

"To explain further the critical nature of this setup which would be wiped out almost in an instant if the least suspicion were aroused regarding it, the Battle of the Coral Sea was based on deciphered messages and therefore our few ships were in the right place at the right time. Further, we were able to concentrate on our limited forces to meet their advances on Midway when otherwise we almost certainly would have been some 3,000 miles out of place.

"We had full information of the strength of their forces in that advance and also of the smaller force directed against the Aleutians which finally landed troops on Attu and Kiska.

"Operations in the Pacific are largely guided by the information we obtain of Japanese deployments. We know their strength in various garrisons, the rations and other stores continuing available to them, and what is of vast importance, we check their fleet movements and the movements of their convoys.

and the later of

"The heavy losses reported from time to time which they sustain by reason of our submarine action largely results from the fact that we know the sailing dates and the routes of their convoys and can notify our submarines to lie in wait at the proper point.

"The current raids by Admiral Halsey's cerrier forces on Japanese shipping in Manila Bay and elsewhere were largely based in timing on the known movements of Japanese convoys, two of which were caught, as anticipated, in his destructive attacks.

74

\* \* \*

"The conduct of General Eisenhower's campaign and of all operations in the Pacific are closely related in conception and timing to the information we secretly obtain through these intercepted codes. They contribute greatly to the victory and tremendously to the savings of American lives, both in the conduct of current operations and in looking toward the early termination of the war."

\* \* \* 4

What I am going to say next is very important. The interception of foreign communications and subsequent processing requires the services of numerous communications and other trained personnel. In order that the product may be most useful operationally, and not merely historically interesting, the intercept traffic has got to be forwarded as expeditiously as possible to the processing center, and after processing the COMINT product must be promptly transmitted to the people who evaluate it from an intelligence point of view, integrate or collate it with intelligence from other sources, pass the results then to other intelligence personnel, and, in some cases where it makes a difference — a great difference, seconds perhaps — see that it is transmitted direct to operational commanders. The need for trained communications personnel, intelligence

REF ID:A66402

experts, radio and electronics engineers, mathematicians, linguists, cryptanalysts, and other highly skilled personnel, military and civilian, is therefore quite obvious. It takes a large organization. In 1939 or 40, the totality of personnel in the Army and Navy devoted to this work was about 300. In 1945 we had 37,000! That gives you some idea as to what it takes, aside from millions and millions of dollars for equipment, both communications equipment and this type of equipment that I gave you a little story about.

. J. 1

Some of the cryptanalytic and communications intelligence processes can be accomplished in the field to meet certain immediate needs of field tactical commanders, and these have been provided for by each of the three Services in order to meet special needs in this category. But communications intelligence processing involves a rather large and intricate complex of a good many activities, much of which can be done well only at major, large processing plants where the limited number of highly skilled personnel can be concentrated and very special specialized cryptanalytic machinery can be installed and maintained. You see, we have too concentrate the skilled personnel because there are only a limited manber of them. You can't find people trained in this field in civil life, because there is no need for cryptanalysis in commerce or industry, so that when war comes we don't have a large pool of trained civilians from which to draw to augment our forces. We've got to take basically intelligent people with pood backgrounds, and good education, and train them curselves. The clearance process alone takes months, and while during that time we can give them some basic training, the more. complex phases have to be absorbed largely by on-the-job training.

Now, I want to say a few words about the very great importance of coordination of communication intelligence activities with other intelligence operations and the tactical situation. There you've got to have certain cover methods. For example, when a decision has been made to take action based upon communications intelligence, a careful effort must be made to insure that the action cannot be attributed to communications intelligence alone. Otherwise you will kill the goose that lays the golden egg. When possible, action must always be preceded by suitable reconnaissance or other operations which will serve as cover or deceptive methods. For example, if there is a convoy out in the middle of the ocean and suddenly it is attacked by air, the question might well rise, "Well, how the hell did they know we were out here, way off the beaten track?" You see, you make cover for that, perhaps by air recommaissance — or it seems that way to the enemy.

Another aspect of coordination between operations and communications intelligence is to be mentioned. The communications intelligence producers must be carefully and fully oriented to give optimum coverage of tactical operations in progress, or contemplated. There are just so many facilities and personnel available for communications intelligence work, and there's a great deal of traffic, an enormous amount. Only a fraction of it can be processed, so you've got to neglect the rest.

It's essential, therefore, that the communications intelligence workers be abreast of the current situation so that they'll know where to put their maximum effort. Also, their knowledge of the tactical situation is essential to a proper interpretation of certain results they obtain.

N 35 2 8.

It's importent, also, to correlate the communications intelligence work with tactical operations in another phase of operations. If in exuberance our bombers knock out enougy radio stations, the very success of such an operation has repergussions upon communications intelligence. You see, putting those stations out of business makes unavailable to us a lot of traffic; so that operations of this sort must be coordinated with the COMINT authorities. There is another reason for being very careful to coordinate, and that is that cryptosystems are usually world-wide or area-wide in distribution, and if you don't coordinate tactical operations with your COMINT authorities, so as to cover up your source of information, the enemy will soon suspect that his cryptosystem has been compromised which would have far-reaching consequences. You see, a commander who is a recipient of COMINT and seeks a minor advantage by using it in one locality may deprive commanders in other areas of much greater advantage; you want to be sure that you don't compromise the source of information that's the important point in this discussion. While knowledge and experience point to the necessity of exploiting every possible advantage that the situation affords when you get this stuff, and in the heat of battle the temptation is, of course, very great to use the material whenever it is available, nevertheless this often may lead to carelessness in its use, which may lead to jeopardizing the source. Of course, the full value of communications intelligence cannot be realized unless operational use is made of it. However, when action is contemplated based upon such intelligence, the possibility of compromise of the source must always be

## SECRET

borne in mind and the danger weighed against the military advantages to be gained. Minor advantages never alone are sufficient ground for risking the loss of the source. Yoursendo, Courton in Santage

Well, gentlemen, it's 10:00 o'clock. I'm sorry that we don't have any time to enswer questions, but I welcome you to examine the exhibits. If I can answer a question while you are doing so, I will be glad to do that. Thank you very much for your courtesy and your attention.

And our count

COMMUNICATIONS INTELLIGENCE

A presentation by Mr. William F. Friedman to the faculty and Students of Class 50-B, Air Communication & Electronic Staff Officers' Course, on 29 September 1950

Colonel Sheetz, Gentlemen's first I want to assure you of my appreciation of the opportunity to come to talk to you on my subject. In inviting me to speak on the subject of Communications Intelligence, it was indicated that the objective of the presentation is to create an awareness of the background, development, and manner of employment of this vital military weapon. Communications Intelligence was not always regarded as vital. I am reminded of a story that I read some years ago in an old book, and the story may be apocryphal, but I give it for what it is worth. It seems that about two thousand Semiramis and who years ago there was a Persian queen whose name was Simarlus. The took an . Whereir it was because of that interest on other ministeral wice interest in cryptography, apparently, and she died. Presumably she went to Heaven, or perhaps to the other place, but she had left instructions as to the disposition of her remains, and they built for her an imposing mausoleum in which her sarcophagus rested. On the outside of the mausoleum there was carved a message, and the message said, "Stay, weary traveler if thou art footsore, hungry, or in need of money, unlock the riddle of the cipher graven below, and you will be lead to riches beyond all dreams of avarice." Then undermeath it the possibility of sudden wealth served as a lure to there was this cryptogram. For several hundred years all the experts tried but they were. their hands at deciphering this message without success, until one day, prealong came sumably, a long-whiskered, bespectacled individual came-along and after working at it for a considerable length of time, solved the message, which gave him cletarled for making.

instructions as to a secret entry into the tomb. He got inside and then found

REF ID: A66402

in order to do so.

an instruction to open the sarcophagus, but he had to solve another message Possibly it involved funding the Covered combination is a 5-tumbler like which he did, and opened the sarcophagus and found a box. In the box was a message in plain language, and this is what it said: "Oh, thou vile and insatiable monster, to disturb these poor bones. If thou hadst learned something more useful than the art of deciphering, thou wouldst not be footsore, hungry, or in need of money." Many times in the course of the past thirty years I have had occasion to wish that I knew the old gal's address so that I could put as a first indorsement to the basic communication the single word "Concur." Well, anyhow, it's been an interesting life, if not financially lucrative.

Now I am going to read you a little paragraph from Time dated December 17, 1945. "Magic is the Word for It" is the title of the article. "U.S. citizens discovered last week that perhaps their most potent secret weapon of World War II was not radar, not the VT fuse, not the atom bomb, but a harmless little machine which cryptographers painstakingly constructed in a hidden room in Washington. With this machine, built after years of trial and error, of inference and deduction, cryptographers have duplicated the decoding devices used in Tokyo. Testimony before the Pearl Harbor Committee had already shown that the machine known as Magic was in use long before December 7, 1941, had given ample warning of the Japs' sneak attack if only U.S. brass hats had been smart enough to realize it. Walks, General Marshall continued the story of Magic's magic. And then it goes on to say what that story was, east I hope

I hardly need to stress the necessity for secrecy in this business. Hope for future success depends to a very great degree on maintaining secrecy with respect to past achievements. Changes as a result of suspected compromise of

of leakage or compromise are not local - they are widespread, because of the widespread use and distribution of particular cryptographic systems. During World War II, I might say, the continuance of our success hung by a very slender thread. I am reminded at this point of an instance - this was before the ward and to avoid naming names I will simply say that there was a chap in a certain capitol of the world who sent a message to his home government in which he said that he was getting a bit worried about their communications. He said "You know, these many exchanges that we are having dealing with this matter in hand, have made it necessary to be very voluminous in our correspondence, end, other

I am a little bit afraid that perhaps some third party might be able to reading the communications. Well, we read that, and we were very much upset for fear something would happen and so we were on tenterhooks and pins and needles for

two or three days until we got the reply from headquarters. To paraphrase the reply, it said, "Well, you southern extremity of a horse's anatomy, don't you realize that what you are saying is out of line? Don't you know that our system has so many permutations and combinations it's inconceivable that anybody should be able to read these communications without having the key? Now, don't you worry any more about it. You tend to your own mission, and we'll tend to ours." We were very happy when we read that one. The Aread was unlocked.

ours." We were very happy when we read that one. The Arrival was provide to do quite a very thing because it was provide to do quite a limit hardly need to give you a definition of communications intelligence, or COMINTAL we call it for Short. To doubt the Major Morrison has already dealt with it, and I will simply cite the three main objectives. First - to provide authentic information for policy makers, to apprise them of the realities of the international situation, of the

war making capabilities and vulnerabilities of foreign countries, and of the

on can magnie hour agos with excitement we will the blessage was placessed to the point

o some we

intentions of those countries with respect to war. Second - to eliminate the element of surprise from an act of aggression by another country. Third - to provide unique information essential to the successful prosecution, and vital to a shortening of the period of hostilities. Now, the background of communications cations intelligence, which is based upon the science of cryptanalysis, forms very interesting history 😿 is inextricably bound up with the history of cryptography. The two are but opposite faces of the same coin, rogress in one inevitably leads to progress in the other. Hence, while my talk is to be devoted largely to cryptanalysis and communications intelligence, I will have to deal also with cryptography and communications security to a certain extent. . of compec. Now, because of the secrecy or cloak of silence which officially surrounds the whole field of cryptology and especially cryptanalytics, it is obvious that authentic information with reference to the background and development of the science in foreign countries is quite sparse; and although after World War II the accomplishments in we learned much regarding this field of work by our enemy, security rules prevent my saying very much about them. I can only give a fairly good background of U.S. activities, and even then I will not be able to say very much about the U.S. Navis Company. ROMINT meety activities, because I don't know very much about that background and prefer not to give any information that I can't document. In any case, I might say at this point that our relations with the Navy in the early days were such as to preclude my knowing very much about what they were doing, and the same of eryplanalysis, Some vice versa. In the course of my talk I will give illustrations, many of which form part of my own experience. Modesty would dictate their omission, but because of their possible interest I will use them and will here and now make a

-4-

general apology for the use of the personal pronoun.

Now may we have the first slide, please. Cryptography and cryptanalysis go back to the dawn of the invention of writing, and here I show an instance of cipher in the Bible. In Jeremiah 25:26 occurs the expression "And the king 51:4: "How is Sheshakh taken! of Sheshagh shall drink after them." Also in Jeremiah. Well, for many, many years that word "Sheshagh" remained a mystery. There was no such place. But then somebody discovered that if you write the twenty-two letters of the Hebrew like this, alphabet in two rows, eleven and eleven, you set up a substitution alphabet

there standing opposite them. "Shin"

whereby you can replace the letters by equivalents. For example, "she" is represented by "beth" or vice versa, so that "Sheshach," translates "babel", , ... mentioning the Bible, one moths by that "Babylon." The vowels had to be supplied. Incidentally, Daniel, who was the first psychoanalyst, was also the first cryptanalyst. I say psychoanalyst, Analyst. The Cible's own words

facedamonious or

which is the spitalae used by the ancient Greeks. They had a home cyling of the dimensions, der of most around which they wrapped spirally a piece of parchment; and they then the least of the parchment, uncomment them, and sent it to would wind the parchment them, and sent it to would wind the parchment around its destination, where the recipient, having an identically dimensioned and thus bring together properly the letter representing cylinder, would be able to recenstruct the message. This diagram, incidentally, is not correct. The writing was done along the edges of the parchaeout before, and not so shown in this paretime. And, by the way, ment, Incidentally, the baton which the European field marshall carries as one

of the insignias of his high office derives from this instrument.

a very simple method, medically because all he did was to replace each letter by the one that was fourth from it in the alphabet. Cicero was the inventors of what is now called short hand. He had a slave by the name of Tero who wrote for Cicero his records and so on in Tirronean notes, as they are called.

Papal states about 1400. I show next an alphabet of the period of 1400 which is interesting merely because it shows that in those early days they already had a recognition of the weakness of what we call single or monoalphabetic substitution, solution, effourse, is accomplished by frequencies. I don't have to go into that. I think all of you at some point have had some contact with that sort of thing. But have is a method of disturbing the normal frequencies, by having the high-frequency letters represented by a multiplicity of

this plide show root the carly Italian cryptographers introduced

## Twice and that SECRE

characters. New the earliest tract that the world possesses on the subject of cryptanalysis is that which was written by a Neappolitan, whose name ats forthe the primiples and was Sico Simonetta. It was written (in 1474). He describes the methods of solvhe describes them ing simple ciphers / no doubt, but in a very clear and concise form. book, extensive treatise on cryptography is that by a German abbot named Tritherius, who wrote his monumental work in 1531. He planned to write four 'he perposely wrote to obscurily and made push fantaine claims that volumes, but he quit with the third one because somehow or other he got charged with being in league with the Devil, and they burned his books, as a matter of more. recent fact. 14 We are going to jump a ways now to some example's from history. shows a cipher alphabet and system used by Mary, Queen of Scots, in the period 1545, or thereabouts. There was an Italian cryptographer whose name was Porta and who wrote a book published in 1563, and in it he showed certain types of alphaand are denoun bets which have come down in history now as Porta's Alphabets. That's an exampof the Porta Table, showing,"
le taken not from his book but it shows one alphabet with key letters/ a or and so on. b, another alphabet with key letters c or do. I don't want to go into exactly how those key letters are used, but it is sufficient to say that even to this day the Porta alphabets are occasionally encountered. Incidentally, Porta was quite a fellow. There are lots of people who refer to his book but have never read it. I took the trouble to have it translated to see just what he did say, and he was, Arabably, in my opinion, the greatest of the old cryptographers. Incidentally, also he was the inventor of what we know as the camera obscura, the progenitor of our modern cameras. I think also he was the earliest of the ruptanalysts alle to solve a system of key substitution, where the key is changing constant Porta's table was actually used in official correspondence. picture of a table that was found among the state papers of Queen Elizabeth's

7-7-1

REF ID:A66402

used for time, communicating with the ambassador to spain. It was fortain alphabets. The next slide I show is the second Vigenere Square or Vigenere Table; a set of twenty-six alphabets all displaced step by step, with the plain-text of the square the table letters at the top and the key-letters at the side, and the method of using is of the plan-text letters to which causes to take a key word, and the equivalents change in each alphabet according to the manner in which the key changes. Now, Vigenere also has an interest to me bereally didn't and whate cause although he is credited with having invented that square, he never said Herdo he did never made any such claims. That's a picture of it as it appears in his book, and it goes considerably beyond what the ordinary references say about his table I won't go into those differences They're technical and perhaps of no great interest to us today.

The next cryptographer I wish to mention is a Frenchman, François Vieta, an emminent mathematician, founder of modern algebra. In 1589 he becamp Counseler of Parliament at Tours and then Privy Counseler. While in that job he gened scovered the key to a Spanish cipher of more than 500 characters, and then all the Spanish dispatches falling into French hands were easily read. Phillip II of Spain was so convinced of the safety of his cipher that when he found the French were aware of the contents of his letters to the Netherlands, he Vieta was called on the compet and made to explain complained to the Pope that the French were using sorcery against him. Here is of another old official cipher. another example. Here are the alphabets; and a sliding card, which could be shifted up and down, was used as a changing key, a method of changing the key. Here is another called the two-square cipher, two-alphabet cipher; weing coordinates again, but there is one complete alphabet and there is another one; and the coordinates are used to represent these letters. That was actually used in Charles Istime, 1627, communicating with France and Flanders.

-8-

Period of the American Parolution

I want to jump now to the evolutionary War period in U.S. history. The systems used by the Americans and by the British were almost identical. In I have seen references to an one case, in fact, they used the same code book. It appears that there was an who peems to lave bean the Revolutions AFSA, for he and it is claimed that American whose name was lovely who was the cipher expert of Congress, who managed to decipher nearly all, if not all, of the British code messages intercepted by the Americans. The next chart shows a picture of a code or syllabary, as the so-called we call it, used by Thomas Jefferson. This syllabary is constructed on twopart principle. This is a section of the decoding velume. You will note that the numerical groups are in consecutive order but their meanings are at you have to have another section, They have no alphabetical order at all. It simply means that in the encoding section, the words are in alphabetical order, and their equivalents are in random order. A system which even today sees extensive use. Jefferson was an all-around genius, and I shall have something to say about him and cryptography a little bit later on, I hope. Here's an interesting slide showing a picture of a letter which is known as the Benedict Arnold Indecipherable treasonable Cow Letter which has never been deciphered. It reads, "I have bought a cow and calf from Gen. John Joseph Burlesca," and so forth. The reason that it hasn't been deciphered is that there isn't enough of it to form the basis for a solution. "I am going to say a few words about Egyptian hieroglyphics for the and a great reason that I think that that represents the next, landmark in the history of cryptography. About 1821 a Frenchman, Champolio, startled the world by beginning to publish translations of Egyptian hieroglyphics. This is a picture of the Rosetta Stone; Egyptian hieroglyphics decoded to Egyptian and then Leting, the Egyptian hieroglyphic witing and it was by means of this inscription that this was finally solved, E reprethe successful socution to sented a cryptanalytic problem, In the hieroglyphics there are things that we

all these lets were assumed it to be to say the Same Hing, of course.

characters enclosed in a rectangle marked call cartouches, that is, things surrounded by a graven line. Here are some Lew examples. This was on an obelisk, and this cae was suspected of reprethat assumption senting the name Cleopatra, and I suppose the reason for suspecting it was the repitition here of two characters at a proper distance to represent the two A's of Cleopatra. By taking the various cartouches, writing them out carefully, cartouche studying them on the basis that this was Cleopatra, it turns out that by takcharacters with controller their Roman letters ing the letters and substituting its equivalent, and putting them in the proper names other than Chopatra, such as places, bit by bit Champolio was able to establish other names, like Ptolemy, a start or initial break was made with respect to and Alexander and so on. That's the way in which the Rosetta Stone and Egyptian hieroglyphics were finally read. It was very fortunate that the early didn't know مديمه Atudants of Egyptology had not realised that the Egyptians used cryptography. "plain-text Some of their writings are not only hieroglyphics but they are also cryptofierographic. Here for instance, are not only nierographic, but they are also cryptographic entities is an example of substitution. That character in place of

Now I am going to jump to the American period of the Civil War or the War Between the States, Here is a picture of a cipher device used by Confederate Army captured at Vicksburg, one of treasures. The method of use of this is a cylinder covered with a sheet of paper bearing alphabets, the alphabet Vigenere table, in other words, a pointer that you could slide and a thumb with which the alphabet according to the key letters.

this one means to speak. You see the finger pointing to the mouth, and so on.

There is one person I passed over in getting to the Civil War period. Ed-

gar Allan Poe in 1842 or thereabouts kindled an interest in cryptography by his story of "The Gold Bug" and by a couple of articles in journals dealing without question.

Here is a picture of a message, authentic, which was sent by President Lincoln to Gen. Burnside, and It's very simple. It reads this

-10-

\_ REF ID:A66402

it makes excellent seuse: way, of course, but if you read it backwards, "If I sould be in a boat off Aquia Creek at dark tomorrow, Wednesday / evening, could you without inconvenience meet me and pass an hour or two with me? (Signed) A. Lincoln. the President was kidding a bit. This is a photograph of a page or two from the code book and cipher system used by the Federals. They had what is called to be followed thing and transcribing the words of the massage. Here's how you write the message in; the first word, second, third, fourth, fifth, sixth and so forth; at then take it out according to another route. And here the thing is complicated by the use of arbitrary equivalents for the names of important people. "President of the U.S. is represented by "Adam" or Asia. It had two equivalents, you see. Here are some of the famous names of s or well-league officers of that period. I have with me today the complete set of books used by the Federal Army during that period, and after my talk those of you who wish may come up and examine it, together with certain other exhibits. Next See is a picture of a message sent to General Grant in that route ciphers. I shall not take time to read that. There is an example of a type of secret writing employed by the French in the Franco-Prussian War. It consisted of code groups written out from a code book. You remember that in the Siege of Paris The had to be sent not by pigeon. The message so that they were completely cut off, and the message was them photographed down, and this, Ibelieve, the was the first and earliest example that I know of of micro writing used for the message was, as I said,

military purposes - photographed down and sent out by means of carrier pigeon, and this is a copy of one of the examples.

After the Civil War or War Between the States, the use of cryptography in the United States military affairs went into a decline for a long period of peace, and was broken only briefly by the Spanish-American War. The War Department published a code called "Code to Insure Secrecy of Telegrams;" in 1885.

based on a small commercial code, almost word for word. It was a dent have a copy of that with me. In the Spanish-American War there was very lit-- for we use made of sound : tle cryptography, when used that code which had no secrecy whatever; but then in those days, when. we must be manber there was no such thing as radio. In 1899 the Chief Signal Officer undertook the preparation of a suitable code. Economy was stressed - the Chief Signal Officer personally did all the work. In 1902 the eigher of the War Department was published by the Adjutant General. In 1906 a revision of that was published, and in 1915 a completely new code, War Department Telegraph Code, was published. believe it or not, that code was and printed by a commercial house in Cleveland. We come now to the World War I period with Hertz's discovery of the so-called Hertzian waves and Marconi's practical demonstration of signalling by wireless; a new era in military communications was ushered in, and also a new era in cryptology. The first wide usage of wireless, or radio, as it soon came to be called, was in World War I, but developments in cryptography lagged a bit, as we shall see. in whee was I

First, I will discuss the tactical use of cipher systems, because these were used in preference to code systems, which came later. Here is a picture You will note that it is of a cipher system used by the Russians. Nothing but the Vigenère system all for it represents allo over again, but using numbers instead of letters Hore is a case involving a repetitively, by a key number. set of 7 or 8 alphabets used for substitution. This was the deciphering used by the Franch at was The mext ene is a picture of a front cipher system, a transposition transcribed according to the columnar best; system, the Mey columns being here and in addition certain disturbing elements came into the method by taking off the letters in diagonals. And that is a picture of the system used by the Italian army in World War I. Again, it is only a variation of the Vigenere system. And Here is a system used by the Germans, invented by them, or refly, I should say, it was a combination of two methods put together in a

very clever way. We called it the Appendix cipher because the cipher text con-

sisted exclusively of those letters. An alphabet in here arranged according ADFGYX; the letter of the to some ng-order, with the coordinates ABSGEM, you enciphered your message fre sample, were then replaced by paro of the by obstituting the coordinates with the letters, as you The letter a numerical r is represented by Z and so forth, end then you write a key developed from the are them taken is written key word, over your X's and A's and so forth, and take the letters out in columns according to the key order. That was a brand new thing in military arrairs for the Allies cruetanalysts and caused no end of headaches until it was discovered just how the solution could be achieved. In that case, the solution was not a general solution but cases but these Lappened so offen they we could bende on them depended upon special instances, and I den't have the time to go into that. Aystem That cipher was used by the German high command and consequently someone soon discovered that you made a chart based upon the number of ADSCENT messages intercepted, why you could discaver certain things about the tactical situation and especially about what might happen. This is a chart which we got up in the ADFGVX
AEF based upon the ADSGEX intercept. This, gentlemen, is the first illustraone of the basic principles of next slide gives a picture of the sort of thing that we put out, a bulletins **ADFGVX** that we put out when the ABSOBE messages were read, and there are a set of messages from November 20, 1918; of course the war was over, but this gives very into Koumania Mackensens important information about the withdrawal of MoHenegals army. There is the German text and there is the translation, an authentic message. The British The For tached massages in words was I Last Last and Americans used a eipher known as the Playfair cipher, invented allegedly by Lord Lyon Playfair, but he didn't invent it - Sir Charles Weatstone invented Dequare 5x5, in Which you start in with a it. The method of encipherment is to have a key word, then the rest of the let-( I and I are treated Bas the Same / letter.

ters of the alphabet, and If you wanted to encipher "at" the equivalent in the way Wheatstone who is credited with wwenter the electrical budge that its known by his name at 3-4 unicent that budge - a chap named Christy really that.

In those days, 1914, that was regarded as pretty hot stuff. In fact, an officer of the American Army later became Chief Signal Officer, Maj. Gen. Motorre, wrote a little treatise published in 1914, in which he dealt with this Playfair cipher system, which the title of his work is "An Advanced Problem in Cryptography." Today, our most elementary students are given things of that sort to solve. The British Army proposed a cipher device in World War I, and hey had manufactured a great many of them and distributed thousands; of they proposed to the French and the Americans that they use the same thing for tactical communications, but it was never put to use for reasons that I hope to tell you later.

in World War I. Now, I'd like to say a few words about codes and code systems used. think you all know that a code system is simply a sort of dictionary in which the words, phrases and sentences are representable by arbitrary groups of let-Here is a page from a commercial telegraph or commercial cable company's codebook, that they offer to their customers. You'll notice that each of these code groups differs from every other code group by at least two letters. for hairing such a differential.

The reason is that it orrer is call that the two-letter differential. errors are sometimes made in transmission but in transmission, the liklihood of making two errors in the same group is not The 2- letter differental afferds nearly as great as making a single error, and their methods of correcting actions by the contracting actions to the contraction of the contraction and their methods of correcting actions to the contraction of the contracti with a let more trouble 2-letter pros can also be coincited. matically a group if it has a single error in it. Now, code books and codes are made suited to the kinds of business. They are specialized on generalized, like a shipping code, or a code for the automotive industry, and so on The next one is the highly specialized code. You know, there are certain people who believe firmly and implicitly in the power of healing by suggestion and

but they may also be lugally appearates in

and what not, and here is a picture of a code book put out by a gentleman who was a professional man in that field. You'll notice that the purpose of it was, of course, then if you want on a trip and want to consult your practitioner you could send him a message and tell him what you thought you were suffering from. Of course, you thought you would simply represent your other thing. It was English and French, and you would simply represent your illness, or alleged illness, by code group. Now, note that the gentleman who got up this code was pretty well versed in the intricacies of code and communications difficulties, because these code groups differed by at least three letters each; and the reason, of course, is that it would be a pretty serious thing if you sent a message saying that you were suffering from come but get the product of convulsions. That would be pretty tough.

Prior to World War I the use of code books for tactical purposes was thought
to be impracticable, largely because of the question of compling, he produced
the possibilities of solving code, the Early in 1916 the Germans began to use
field codes, and the Allies soon followed suit. I had slides to show you pictures of pages of the code books of the various belligerants, but I have exhibits and how would like to see what they were like are welcome to come
up after this talk and examine them. The only one that I make would like to
show is one that will give you a picture of merican indequacy in World War
Communication.

I for code work. This is authentic - I didn't make it up - I found it in the
records. It's a code gotten out by the 52nd infantry brigade dated 17 April
1918, and it is what we called the baseball code. If you wanted to say killed works out, base on ball, this by pitcheball, and so forth - very elementary.

Personal language REF ID: A66402 Now I am coming to a very interesting example of World War I period, a cipher found out of the Consess the Mexican bonder into message which was taken from a German spy in the United States, and he was seen Jerus The message was found on his person, and that's a picture of the code groups and After some weeks it was deciphered by the code-solving organizations in Washington, MI-8, as it was called. Here is the German text, and this is what it said: "The Imperial Consular officials of the Republic of Mexico.strictly secret the bearer of this is a subject of the Empire and travels Yablo Waberski as a Russian under the name of Pevle Beverte. He is a German agent." And so The court peydered lim to be shot president Wilson forth. His sentence was commuted to life imprisonment; and he was out vear! There is a message which is probably the most famous message in cryptanalytic history to date. This is the message which brought the United States into World War I, on the side of Britain. In 1915-16 it was very much catchas-catch-can as to which side the Americans were going to join. Our  $^{
m B}$ ritish friends, and later allies, did certain things that we didn't like, and there was there references behavior a good deal of talk about it. But this message, solved by the British, brought us in. It was the straw that broke the camel's back. It is known as the Zimmermanntelegram. It went to the German legation in Mexico City from Count Von Bernstadt, the German ambassador in Washington. The method of solution I won't Thereleverness in a gord flustration of British go into. The handling of the case shows how astute diplomatically, our friends are, for as I have sheety soid, & reculted , us into the war on their side. were in bringing, the Americans in by means of that message. Here is the transmessage said the Kermana lation of the thing. It was important because they were going to resume the part, Rere, unrestricted submarine warfare and this, dealing with a deal with Mexico, was the straw that broke the camel's back. People in the Middle West were very our gotting into the war - on either side - hit when the Germans luke warm toward the idea of went but when they began talking about siving back to Mexico) Texas, New Mexico and Arizona, that was something else again. So

destablished the authority ID: A66402 within a couple of weeks after the British of talogram we got into the war. PHere is an exemplant another the British and make available to our authorities mercaga me solved in World A this time by the United States group in Washington; a sabotage message talking paloteurs were about who was reliable and what they should do and that figured in a long, long German-American Mixed trial before the \_\_\_\_\_ Claims Commission, in which the termans were charged with certain acts of sabotage, notably the Kingsman fire and the Black Tom New Janes, Wash of your are too young to know those medeuts. The trial explosion, and the resulted in a decision in favor of the United States, claimwho were amanded ants, some \$40,000,000. This is a message, in secret ink, that figured in the Black Tom Case; a page from the Bluebook Magazine, an which there was exerciunitar in invisible into the method we run into occasionally even ~in modern warfara. Now I come to a case in which I was involved. In 1915, no, in 1916-17 the Germans financed a large number of Hindus in their attempts to stir up a the Buch rebellion in India, the idea being to cause so much trouble in India that it be forced to withdraw to quell disturbances in didea would draw out British troops from the Western front, and these Hindus were negotiating for the purchase of arms and ammunition in the United States and sending # over to India. Here is one page of a long, seven or eight-page mee that was intercepted between the Hindu in the United States and his chief in Switzerland. The message consisted of groups of figures, which were interpretty quickly that the letters of the secret xet had the some plain - text spersed with words. I recognized immediately that this represented the page of spersed when words. I recognized the position thunder in the line; and All I needed a book, this the line number, and this the letter in the line; and All I needed was the book, but, of course; the message iteelf didn't was what the book was, was the book, but et course, the methode unterit so I had to go ahead and try to solve it. This was solved, and I'll show you very briefly the method. As I said, there were words, plain-text words, interthroughout the cipler jest spersed, and I would make a guess. Here, for example: "Formedam / something, with something." I assumed that this would be the word "committee," and that meant that on page 65, the fourth line, the second letter in the line was a C; at what the numerical roup before or after a of the letter. Merresented.

REFILID 1826 5002 I, To and so on were taken.

well, the third happened to be 0 and the fourth or M, and the fifth an M,

but the sixth was not indicated and so on. Well, by substituting some of these
guesses in their proper positions and tabulations of this sort, I found that the
this word committee came from the word communication on page 65. Then this

· Petter in that live

word is "Attention," and se ca. And by working back and forth, building up wares words on varia the pages of the book, and building up the message - one helped the other - a I finally came to the conclusion that it was a book dealing with the history of German political philosophy, or what not, and I hunted and hunted and hunted. I finally found the book, all right. It was Price Collier's Germany and the This message figured in a trial set in San Francisco, where there were about a hundred and five Hindus on trial simultaneously. One of the Hindus turned 3 tate's evidence and got himself in bad with the others. They were searched every day before they came into the court, but one day, the day after I testified, one Hindu managed to secrete a gun in his clothes and during the midst of the proceedings shot the Hindu who had turned State's evidence, whereupon the United States Marshall, a great big fellow, six feet four, standing in the back of the court drew his weapon and shot the first Hindu dead. They were both dead right there, within two or three seconds. That's the way that trial ended up dramatically. over the next slike. It

I'm going to pass that ene up. That figured in the oil scandal in the days of 1924. I was government witness in that case, solved the messages and which desclosed has ure showed some of the facts that lead to Mr. Fall's going to prison, the Secretary of the Interior, I was all. I think the deal only resemble.

The rum runners in those days used some very good codes and ciphers. Here is a particular case where a message was enciphered by taking code groups out of one book, transferring the code numbers for the groups into another book and

SECRET

00

Mas

trose letter

then adding a constant value to those numbers, and this was the message. All I had to do was to find the books, the additive, and the cipher dependent.

There were some interesting things, working on the job we would get messages from various government agencies to solve. Here is one that came to the works.

White House and sent to Secret Service. It was addressed to the President and had this stuck in and after this figure and all it was was If you read it backtake asked (headed foosself: wards and alternate letters it says "Did you ever bite a lemon?"

Now I am going to jump to the question of cipher devices because they represent the modern trend. I've already mentioned to you'the effect of the entroductori into wide usas invention and distribution of radio, and its effects especially upon cryptology. Traffic in large quantities became available for interception and study, and hence improvement in cryptography had to come. It came slowly but surely. In in cryptographic methods connection with theoretical advances came inventions of cryptographic devices the brief history of these will therefore be useful. picture of the earliest cryptographic device on record, except for the spi This is taken from a book by an Italian named Alberti, published in 1470, and is just a cipher wheels one revolving concentrically upon the other, so that you could change the relationship of the alphabets. This wheel is represented also in the Porta book, and, by the way, I have a copy of the original edition of Porta, with the cipher wheels in place and in working order. This was published in 1563. They didn't have any children in those days, obviously, or otherwise these things wouldn't be here, and in spool working order!

I know it takes a long time to get a patent through the patent office, but

Alberti's device was finally patented in 1865, the inventor happening to the

Albert J. Believe it of the Chief Signal Officer of the Army, at that time Major Myer. It was the same

thing used by the United States army in the period 1910 to 1918. There is a more recent invention of the same thing. The patent office doesn't have good access to literature on the subject, so every once in a while a thing that is as old as the hills gets through the patent office. Now we come to andevice I mentioned that the British proposed a cipher device for use on the Western Front in World War I, and a little bit of history of that is interesting. Here is a picture of a device invented by Sir Charles Wheatstone, the emminent

British mathematician, physicist and electrical engineer. The principle is a little different from the preceding one. This had an alphabet of 27 characters and an inner alphabet of 26, with an eccentric motion depending from the letters that you were actually going to encipher. With this hand, you see, you go around this way, and the fourth revolution, for example, if the letter H is represented by E on the next revolution H would be represented by the next letters, which happens to be a victor. Now the British took that basic inventions and the factor of the letters of

tion, and vental noticed that the first slide has the alphabet on the outside.

Entire the the mineral source in mixed order, in normal order. What they did was to add the idea of a mixed alphabet on the outside. They changed the form of the device itself, but the cryptographic

principle is identical. They had a great many of these manufactured. I was at that time, working at the Riverbank Laboratories, and his thing had been approved by the British, the French and the mericant in Europe. It was sent to Washington, approved there by the MI-8 people, and somebody there said, "Well, let's see that this fellow out in hicago thinks about it so they sent me a

set of five test messages in this device. All I knew was it was based upon was publish muslick.

Wheatstone principles and by employer came to me one day and gave me these five messages, each message 35 letters long only. He said, "I want you to solve this

SECRET

letter

Its abound and unfair I da thing." I said, "But I can't solve anything as short as this. I have other fish to fry." He said, "Young man, on the last day of each month you get a little green piece of paper with my name in the lower right hand corner. If you would like to continue receiving those, you will start work orders right away." I said, "Yes, sir," Well, by hocus pocus which I won't go into, I succeeded in reconstructing what I thought was the basis for the mixing of these the letters of the inner apphabet. secured to be letters in here. The word on which it was based was the word "cipher." and I po for Ao good, but unfoluntly the pulse alphabet by analysis." thought, "Well, there is no way of reconstructing this." At that time I hadn't invented the principle. I later did. There was nothing to do but try to payword for the outer & applicablet made this assumption: guess what the might be, by trial and error, and I tried on this basis. If a fellow was foolish enough to use a word like cipher as the basis for mixing one, held be likely to use an associated word for the basis for mixing the other and I tried every word in my mind associated with the word "cipher, one after to lest south guess. Ithought of words like "alphabet, Aboret, Suf the other, and it took minutes." Then finally I exhausted my efforts, and Mrs. Friedman, who was my right hand man at the time, was sitting in another part of the room, and I said, "Elizabeth, will you stop what you're doing and do do you want we to do something for me? She said, "What?" I said, "Make yourself comfortable. I am going to say a word to you, and I want you to come back at me with the first make a pass or two with her lightle and Load word that comes to your mind." She said, "Shoot." I said, "Cipher." She said "Machine." That was it! In about ten minutes we had reconstructed the alphabet and solved the messages. The first message said, "This cipher is Jelegraphed absolutely indecipherable." We sent the solution to Washington, word got to London, and When I got to AEF in France I wasn't very well liked by our British That Wheatstone principle is attributed to Sir Charles, but not long ago by sheer accident I came across this device it in our museum now n made

a Commandant Bagaries, and but he cartainly made this device. REF 1D: A664Q2 U.S. Army. Wadsworth Willseinson he by a Major Lucius Wadsworth, was aide to General Green of Revolutionary and Jaken Decome Clief of Ordinance. How he became interested in cipher I don't know, fame, and It bears on it - this is a very poor picture - the date 1817, while conceived device Wheatstone devised his and described in 1870. I come now to a cipher allegedly Bazeries derce invented by a Frenchman, Bazarie, called to cipher cylinder. This consists of a shaft on which are mounted discs which can be arranged in keying order, each bearing an identifying number and Harry set up the discs in key order, disc having a different alphabet on it. You line up the letters of your plain my is what it says on this line; indeclifficable" (1) am indecipherable) and for your cipher text message: "Jesuis equivalent you can take any one of the other tenenty five horizontal lines. Rooks a system based upon - if you have the dence. like an excellent principle, but quite readily solvable these days ple, however, was not invented by Bazerie; it was invented by our own Thomas the device which he Jefferson, and there is a picture of his description of a thing called the wheel digging up the facts expher, exactly the same principle. I had an interesting time with that in connection with the definitive additional checks and works being published now In 1915-16 a United States Army officer by the name of Hitt independent at Princeton. wented (again that same principle, this time not in the form of discs, but slida prefine of his ing strips, you see; and this is the original model. Mrs. Hitt came to Riverwhere I was than educating myself in cryptography and she brought along her husband's muchin, s bank, with this thing and said it was pretty hot stuff, and She put up a chalyou might say . Like this : in the dence, which lenge message, and I solved the challenge message by hocus pocus, I thought to Mrs. Hitti is myself, "Well, this lady, beautiful and charming, and so forth, but she doesn't know much about cryptography. What kind of a key would she be likely to use for mixing up the order of the strip? Well, she might use the word 'Riverbank Laboratories. '" That was it: In 1918 that same principle was adopted by the United States Army Signal Corps; there it is, the M-94 device. This, as you uses 25 discs with differentlysee, is mixed alphabets; you can take them off and put them on in any order you please, exactly the same principle. We used that for quite a number of years after a World World CipberDance M-91

-22-

The Navy, the Marine Corps, and the Coast Guard also used it. By adopting with some success. It was not produced in time, however, to be used in Hottis sluding strip form, which lends took better to changing the mixed This, gentlemen, is a picture of the very first SIGTOT or one-time tape cryptographic transmission machine, produced by the AT&T Company in 1918, too late to be used in World War I. The principle is there you perforate your previously-presparate plain-text message, here you have a keying tape passing through a transmitter, voing through author transmitter; there topes are and in the form of here is another keying tape, both different, their loops of their differential Juppose diameters. This one is a thousand characters in length and the other 999. saccording wheators, those You start them out at priven points adjust the positions. These two points won't come together again until you have enciphered 999,000 characters. A pretty good principal, but, again, on a challenge, this was after I came back, was demobilized and then back to Chicago to the Riverbank Laboratories—on a chal-Spokush a Act of messages in the Suplem, without hering the machine with they large lenge, this was supposed to be absolutely indecipherable; said so in writing by a letter signed by the Director of Military (Intelligence, but 1 was able as I have just said, to solve the thing without having the tapes, without knowing how long they the marking. If was a long and were, or anything. There is another interesting solution, but I haven't the time to go into it.

This is a picture of a new type of cryptographic machine. A gentleman Holer.

by the name of Hebron out in California came forth in about 1922-23 with a which acts as a keyboard, rotor a commetter switch was commetator really, the current from the keyboard depressions with this side a fixed commetator going through the wheel here, they switched these circuits, coming out and going through a wheel here, they switched these circuits, coming out and going through a typewriter. Now that machine had only one rotor. In about three or four years, after collaboration with the Navy, he came out with a five wheel machine, five pecitions, you see, and these are the types of rotors that he used, which your

23-

A GO A O Code and a struct The sta thet in the water pretty high security. The Navy was about to adopt these things. They had were about to place a We in the front with Hoberns A didn't even have a dollar contract for \$75,000.00, -coa, how that hit mai at that time! Stribal for that sort of thing. Well, they asked me What about it, and I said, "I'll study it." I came over and I sat before this thing for about six weeks before ubel and I had a really good idea. So I went ever to the chief of the section, and I you'll have to said, "I think I can solve messages," and He said, "Show me." I said, "All I accept your challenge". ,OK. right," He said, What do you want." I said, "I want ten messages set up on your machine." He gave me the ten messages, and I solved the thing. It I'd been working at the proble that happeired to me one evening as was a curious thing. I was getting dressed to go outs of course, it took weeks of making distributions and finding my way around. I had one assistant with chosed-eyed. at the time - he was a veteran, ex-prize fighter, cauliflower ears and all, and he wasn't much help, except in typing. I get to a point where if t could ite problem modernia enly solve of read I had reduced these millions and millions of alphabets 26 letters reduced to a Certain form. to a place where I had one line of about 10 letters. If I could solve that I mentioned, much preoccupied. Well, I would have a start, and I went home that evening from work, and I had a clear picture of this one line, and all I knew was that the first, certain tettes were the some he hands and elevents were the came letters; the second, Trimen many blo Lebters the eighteenth were the same letters: - All certain ones, different—and, of course, I "hapt in mind the specific positions of these letters with my bow tie, it suddenly dewned on me. The phrase that would fit wee ()

The positions of the prepared Subtraction with my bow ties. President of the United States." That was it! The next day I came in verified the assumption. In a few and it a couple of days I handed the Navy a solution; they killed the order. Helieru Nessermo The firm went to pieces; the inventor and president of the firm wound up in a foul of California's blue of years because he sold stock that went to about stock had skyrotheted ! hat the re a share on the bacis that a Navy order was coming through; and when the Navy order didn't come through, the stock dropped to about \$2.00 a For instance the 1st six letters were all different but the 3d, 7th, 14th, 19th, and 25th were idential. The 4th, 21 st, and 26th were identic

and so on . Well, so I said before, while

a share, and to had picked up some of the \$2.00 stuff, went to a different California authorities.

part of the state, and sold it for \$10.00. They didn't like that, so they put him in the hoosegow.

This is a picture of the first cipher machine invented and built in It was sold on the commercial market until the Mazio came Europe, called the Enigma, Commercial Enigma: Here are the rotors, you see; four of them here, a keyboard and the light bank. You press the keyboard, the rotors step, and they light up. You position these things according to keying estroctions letters. Now, also in Europe, after that time there were other inventors. considered to be Here is a machine called the Crenewe which was held as being a very complicated and difficult thing - nobody could solve it. Here is a German professor who put out a treatise on the indecipherability of the thing, showing how many permutations and combinations there were. You could have everybody in could be different there were so many permutation the world provided with a machine and a key, and nobody else would have the and combinations available. same key, and se on. Well, gentlemen, the number of permutations and combinations that a given cipher system affords, like "The Birds that Sing in the pring," have nothing to do with the case, or at least very little. It that is, what they in the all depends upon her those permutations and combinations are basically cryptographically. Here is a picture of a Swedish machine of about the same period; a and a set of The rotors are of a but keyboard; light bank; with rotors, a little different type of mater in type of machine case. Of course, the light bank was slow. You had to sit down and copy by hand and so on; so the inventor of this machine hooked it up with an electric Remington typewriter, and that was the first model of a printing cipher machine. He later modified it so as to have the printing mechanism selfcontained in the cryptograph, and that's a picture of the box itself from the outside; and there is a picture of the internal workings. There is the keyboard.

For instance, take the principle of monoalphabetic nibothution, the principle for used in the Gold Bug. Theoretically, with = 25 letter alphabet, you can make 26! cipher alphabets, now 26! is a large number . 400,000, that is, 403, 291,461, 126,605,635,584; 600,000, that is,

four hundred and three BEE JDOA6640 Ruo hundred minety-one thousand four hundred and surty-one trillions, one hundred twenty-size Housand six hundred and five Billions, six hundred thuty-five thousand five hundred and aightifour millions. Quite a large number. So if you were to
try to solve a capter such as that in "The stock ving" and
where to got at it simply by trying, all those quadrillows
of permutations of the alphabet you'd need late of time
and manpower. Because it has been calculated that merely to with down those permutations it would take a Moresand million men working a thousand million years to do the major part of the job - not all of it - and the scroll would reach from Earth for beyond the planet Mercury! Yet any you can solve "The gold Bus" offer mules, despite the vant number of Openintations that ab 26 slatter alphabet affords.

It's of course, turned eround are here are the switching comutators with pins that you could put in and out effective positions like on our converter M-209. Those pins drive a certain lever, here which drives the switching comutators, which are in here; and you could also switch eround the effects of the comutators. Here is the printing mechanism. This style you'll recognize as being very similar to the style in the Converter M-209. It printed on a tape.

years agas of course, in these days considerable thought began to be devoted to the encipherment of teletype communications, and this was, Aside from that 1802 a few munites ago, ATYT Co. machine that I showed you, this was the first of the teletype cipher attach-developed for Descrit, purposes. It was ments an invention of Col. Parker Hitt, who retired from the Army and joined Where he the International Telephone, Telegraph Company, and devoted himself for two or three years to producing this thing. This was finally, there's the internal mechanism. It had keying wheels which affected the bands of the teletype characters. These wheels were of differential diameters. This one had 101 places, this one 99, this one 97, and so on, down, so that it had an extremely long period; but the length of the period, again, like the birds that sing in the spring, has little to do with the case. That thing was put into test usage in the State Department, and they called upon the War Department to make a security evaluation. I was assigned to the job, and 7 had an interesttime with this. The State Department put up a series of messages. They were stamped in at a certain hour, 10:00 o'clock in the morning; let's say, and about 10:30 the chief of the State Department communications called me and said, "The machine is out of order, Maybe you can fix it." I said, "I'll be up there in a few minutes." I slipped a piece of paper in my pocket, and Rushed over to the State Dapartment, then in the old State, War, and Nary Building. Upon arrival, Salmon was applogation.

, he said. when I got up there, he said, "I'm sorry, "I tried to catch you, but you had already left. It's working again, so I won't trouble you." I said, "By the way, I have a question to ask about those messages." He immediately got suspicious and asked, "What do you want to know?" And I said, "Have you got the away from me, and plain texts to those messages here?" And he drew himself up closes, and he said, "We-el, yes." I said, "Where are they?" He said, "In that safe over there. I said, "Well, I'll sit here. You go over to the safe and dig out message No. 7. I want to ask a question about it. " Very reluctantly he got with his backeto me, the message being a up, opened the safe, pulled out message No. 7, and said, "What is it you want to know?" I pulled out my piece of paper, and I said, "Well, does it say --" in astonia He promptly sat down on the floor, That and I read him the whole message. was only 35 minutes or so after it had been received. The ITT Company butned this development, Le toldyou its fingers on it, gave up the investment and never tried again. So we have and inventing cepter machines, and the AT&T Company studying to code, the IT&T Company; and later on I'll say

failed. The reason is that without emptagraphic and cryptanalytic guidance nobody can invent a thing that is going to stand up under emptanalytic attack by This is onverter M-209 which we adopted: a Swedish invention attack

This is converter M-209, which we adopted; a Swedish invention and is pretty good. The only thing we came across at that time for our floid use in the formula states.

Here are keying wheels. Here is a make which the affected by the keying wheels; the staves as they move to the left; and in number from 0 to 15, which affects a print wheel, and there is the tape. A very neat gadget but a bit plant not too secure when you have two or more messages in the same setting.

Now, the rest of the time I would like to devote to a brief discussion of cryptanalytic gadgetry. This, is a picture of to my knowledge, the first cryptanalytic aid, something I got up at Riverbank way back in 1916, I think it was:

27-

ptrips constitution of

a pair of glass plates with stripe and guides, grooves You could slide these various purposes things up and down to align letters and study them, for what not. I don't know why the hell I put down the United States War College. I had no relations with them, but it was nice to hand them a present, so I did that. I made with my own hands. This was a wheel with rubber letters that I could arrange in to make up alphabeto, any order I pleased, They were removable; there's another view of the thing, and here's a whole bunch of them put together, for whatever purposes you want? te make of them.

Now, from that early start have come a great many very interesting developments. Here is a picture of a thing dated ctober 30, 1934, where sent a menostrudum to Captain King and Major Akin, now Chief Signal Officer, in which I made some remarks. You can see some tear does or maybe blood on this thing. I was asking for a little bit of money to get some IBM machines. I said, "Please do your utmost to get this across for me. If you do, we can really begin to do worth-while cryptanalytic work." Well, the plea was successful - we got it. Here's a picture of part of the contract, you see, the 12th of November. It only took a month. And here is what we were getting, and see these prices. When I think of the missions of dollars which we spent in World War I on this sort of thing, I am amazed that from such lowly beginnings should have come of IBM apparatus that great establishment. This is a room, just one wing in our headquarters during the war, with tabulating machine, here, just one after the other, tabeleting IBM machines to do special purposes, special jobs.

You know the picture the average person has of a cryptanalyst. He's a He has thick spectacles, and whiskers and crumbs in them and so on; he goes into a huddle with himself and pretty soon he comes up with an

answer. Well, that's far from the picture these days. Cryptanalysis and communications intelligence is big business now, and I want to say a word or two about that sert of thing. Cryptanalysis of modern systems has been facilitated, if not made possible, by the use and application of special crypt-

analytic aids, including the use of high speed machinery of the type pictured

Some are machines but mostly we dense and we have recently here, standard, also modifications of those machines, we have recently by

me with any passwell cryptamalytic

the invention, and development of electronica gadgetry. As I said before, the

number of permutations, well, I'll get to that In just a moment. The number

of permutations and combinations in itself isn't too significant. It's what for the structure of their nature appropriate what you are up against a great of they are basically. In modern cryptanalysis what you are up against a great of the structure of the stru

multiplicity of hypotheses that must be tested out, one after the other, until

you find the correct one. This can be done, more calify by these machines, and

high speed sid's combined with statistical matheda. I want to show you what warkings a highly- spaceally some of these look like. I showed you a tabulating section. Here is just one machine for desiphering messages; we call it an "analog "bleause attaget which we call a machine deciphering gadget. That's a specialized thing, pay this:

for how what you try to do in a cryptanalytic practicing center is with a few people duplicate what thousands of people on the enemy side are doing. It

takes thousands of people to put the messages up of the various headquarters in the land on the second of the second of the second on the second of the second on the second of the seco

ber of people to read these messages and process them. If you have the key of key

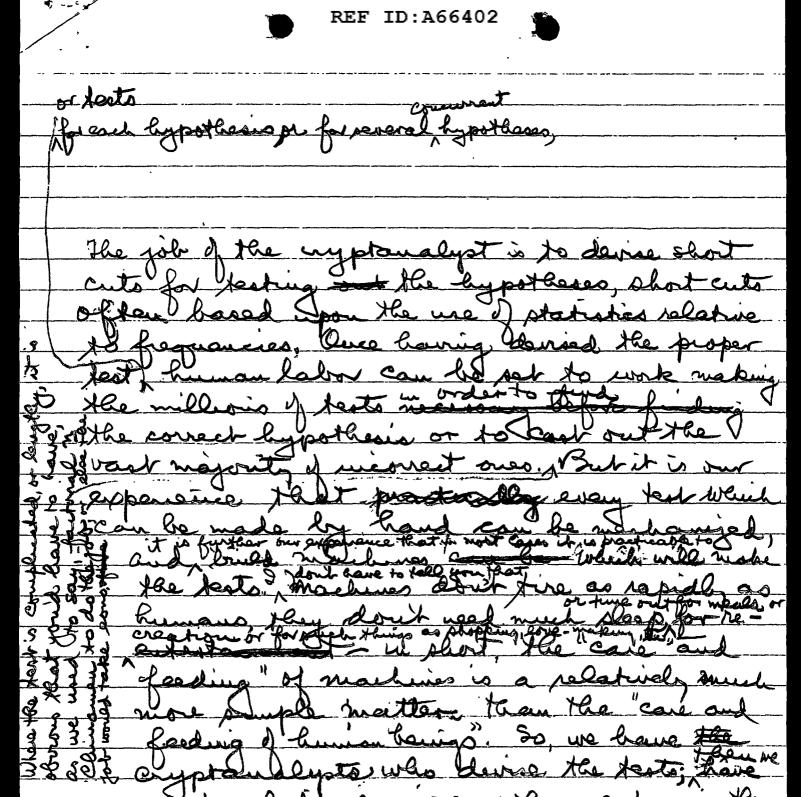

then it becomes a problem of production-line deciphering; so we devises special doubles. As 9 Sand Safata, the Washings machines to take the messages, and decipher them. This may not have any resem-

it duplicates what their machine does, and at a high rate of speed. So that's a picture of such a device. There is a tabulator, standard tabulator with a

cryptosystam does, and resambled to between it land the enemy's machine is puelly coincided tal. To explain, the

teste, de de de de de de la prise, develop uneut, develop and produce the mailines to perform the forts at high speed; then we have

mantanance lengineers who beep the nachines in good working order; Her we

REF ID: A66402 have modiain grader cryptonalytic assistants who examine the output of the markings and who are marked able to take the correct bypothesis or few consult ones and go on with them to the final stage where a pay is recovered; then we may have other harbines which apply the the recovered keys to specific hossages and produce the plain taxts from them but machines per only performante and the band can be performentating at a much slower pate - machines don't, they can't, raplace the thinking processes unvolved in cryptomalysis.

doing "brute force" operations, where you are trying to solve a thing on the which are fair and fractions and millions of letters, the location of those repetitions is a pretty laborious thing if you have to do it by hand, so we speeded to up. A machine of this kind will locate those repetitions say, in one-ten-thousandth of the time that it would take to do it by hand. Here is a specialized machine, again a tabulator, with an attachment, here that is used for passing the text of one message against the text of another message in order to find certain similarities or perhaps pertain differences, and it does it automatically. These relays are set up according to certain circuitry; and you start the machine, and low and behold, it produces a printed record of the message that you get.

Here is a machine which I personally call "Rodin." Rodin was the great confidence of engineering known as The Thinker.

This machine thinks. What it does is you give it a certain number of hypo-

theses and you tell it, "Now, you examine these hypotheses and come up with and which answer." The machine takes the first hypotheses, let's say, and it examines that, and if it comes to a contradiction it says, "Hell, that's no good; I'll go back and take up the next one." And so on. One after the other, at a high rate of speed, are electronic speed. That's only one small section of the thing.

well, we've got left here a few minutes in which I should say something the communication williams about the current employment and manner of employment. You see, I've devoted two hours to talking about the background and development and haven't said warm with about the manner of employment. Well, we could discuss that under the Congressional Committee various headings, but it is obvious from the disclosures of Pearl Harbor, that the manner of employment in World War II must have been very efficacious. I

well

REF ID: A66402 you a pretty good idea of the contribution. which dies bear practically excellent illustrations of the manner of suplay

wish I had the time to read you the whole of the Marshall-Newey correspondence that this article in Time was based upon, but I think that What I am going to say next is perhaps a little bit more important. The interception of foreign communications and subsequent processing requires the services of numerous communications and other trained personnel. In order that the product may be most useful operationally, and not merely historically interesting, the interesting coptions the intercept traffic has got to be transmitted most expeditiously as possible to the to processing center, and after processing the result must be promptly transmitted to the people who evaluate it from an intelligence point of view, and protect or collate it with mitelligence from office powers, pass the require to other intelligence personnel, and, in some cases where it makes a difference, see that it is a great difference # second perhaps - transmitted direct to operational commanders. The need for trained communications personnel, intelligence experts, radio engineers, (electronics) technicians, mathematicians, linguists, and cryptanalysts, and other highly skilled personnel, military and civilian, is therefore quite obvious. It takes a large organization. In 1939 or 40 the totality of personnel in the Army and Navy devoted to this work was about 300. In 1945 we had 37,000. That gives you ar idea what it takes, aside from millions and millions of dollars for equipment, both communications equipment and this type of equipment that Fill give you a little story about. #Some of the cryptanalytic and communications intelligence processes can be accomplished in the field to meet certain immediate needs of field tactical commanders, and these have been provided for by each of the three services in order to meet special needs in this category. But communications intelligence processing in communications in the communication in the

activities, and much of it can be done well only at major, large processing plants where the limited number of highly skilled personnel REF ID: A66402 to be absorbed largely of

can be concentrated and very special specialized cryptanalytic machinery can concentrate the skilled be installed and maintained. You see, we have to have a concentration of the Because personnel, There are only a limited number. You can't find people trained in this field in civil life because there is no need for an activity of cryptanalysis in commerce or industry, and when war comes we don't have a pool of trained personnel in civil life from which to draw to augment our forces. We've got to take basically intelligent people with good backgrounds, and good education, and train them ourselves. The Charance process alone takes wenter, Now, I want to say a few words about the very great importance of coor-

dination of communication intelligence activities with the general intelligence operations and tactical situation. There you've got to have certain cover methods. For example, when a decision has been made to take action based upon communications intelligence, a careful effort must be made to insure that the action cannot be attributed to communications intelligence alone. Otherwise you will kill the goose that lays the golden egg. When possible, action must always be preoperations which will some as cover or ceded by suitable reconnaisance or other deceptive methods. For example, if there is a convoy out in the middle of the ocean and suddenly it is attacked

by air, the question might well rise, "Well, how the hell did they know we way off the beaten track perhaps by air recommunicance - or it seems were out here?" You see, you make cover for that. PAnother aspect of coordina-

tion between operations and communications intelligence is to be mentioned. and fully producers must The communications intelligence people should be carefully oriented to give tacheal optimum coverage of operations in progress, There are just so many facilities personnel an allable for and people devoted to emptanalytic studies in communications intelligence There's just so many available, and there's a great deal of traffic, an

Head way to the

enormous amount. Only much of it can be processed, fou've got to neglect Well, It's essential, therefore, that the expressional the and communications intelligence people be abreast of the current situation so that they'll know where to put their maximum effort. Their knowledge of the tactical situ-. ation is also essential to a proper interpretation of certain materials. important to correlate the communications intelligence work with operations in author
use of peralists. Combern even because if in exuberance our aircraft knock out radio stations, the very success of that operation has repercussions upon communications intelligence. You see; knocking those out makes unavailable to us a lot of traffic; so that has must with the COMINT authorities be coordinated. There is another reason for being very careful to coordinate, and that is that the code systems and cipher systems are usually world-wide or area-wide in distribution, and if you don't coordinate your, operations with your of so as to cover up your source of information, these may be suspicious that his compromised which would have far-reaching consequences. You see, a commander who gets dome of this stuff and seeks a minor advantage by using it in one locality may deprive other commanders in other areas of much greater advantant to be none you hat \_ that the important point in this discussion. tage: If you don't compromise the source of information, while knowledge and experience point to the necessity of exploiting every possible advantage in the heat of battle that the situation affords when you get this stuff, and the temptation is, of course, very great in the heat of bettle to use the material whenever it is available, nevertheless this often may lead to carelessness in its use, which may lead to jeopardizing the source. Of course, the full value of communications intelligence cannot be realized unless operational use is made of it.

However, when action is contemplated based upon such intelligence, the possible compromise of the source must always be borne in mind and the danger weighed

against military advantages to be gained. Minor advantages never alone are sufficient ground for risking the loss of the source.

Well, gentlemen, it's 10:00 o'clock. I'm sorry that we don't have any time to answer questions, right home. I welcome you to examine the exhibits.

All perhaps if I can answer a question while you are doing it. I will be glad to do that. Thank you very much for your courtesy and your attention.
